Abstract

We study the unique 6 dimensional orbifold with chiral fermions where a stable dark matter candidate is present due to Lorentz invariance on the orbifold, with no additional discrete symmetries imposed by hand. We propose a model of Universal Extra Dimensions where a scalar photon of few hundred GeV is a good candidate for dark matter. The spectrum of the model is characteristic of the geometry, and it has clear distinctive features compared to previous models of Kaluza-Klein dark matter. The 5 dimensional limit of this model is the minimal model of natural Kaluza-Klein dark matter. Notwithstanding the low mass range preferred by cosmology, the model will be a challenge for the LHC due to the relatively small splitting between the states in the same KK level.

1 Introduction

Observations indicate that most of the matter in the universe is dark and of non-baryonic origin with a hint that it could be non-relativistic and weakly interacting at late times (cold dark matter). Various potential candidates have been suggested, among the most popular, there are weakly interacting massive particles (WIMPs). In the following we shall focus uniquely on this possibility. This group includes the lightest supersymmetric particle (LSP) obtained by imposing R-parity in supersymmetric models [1]; the lightest T-odd particle (LTP) obtained in little Higgs models with T-parity [2]; the lightest Kaluza-Klein particle (LKP) which is stable due to a residual parity which may survive in the effective theory if special conditions are required for the interactions at the fixed points [3, 4]. Apart from phenomenological considerations, which render these symmetries practically compulsory in all these cases, the most satisfactory way to introduce a stable particle of this type is to consider a fundamental symmetry. From this point of view a residual Kaluza-Klein (KK) parity is the closest candidate, being a remnant of the extra dimensional Lorentz invariance after the breaking by compactification. However, the compactifications considered so far [3, 5] have fixed points or lines which correspond to lower dimensional objects (branes) where the extra Lorentz symmetry is absent at all. Therefore, the KK parity, which is automatic in the bulk of the extra dimensions, has to be imposed by hand on the branes.

We consider these parities unsatisfactory and we want to insist on the idea of keeping a fundamental symmetry as the explanation of dark matter: is this possible? In the development of extra dimensional model building, the idea of branes and orbifolds with fixed points (both suggested by string theory) has proven itself very useful. For example, one can easily obtain chiral light fermions (from a theory which is inherently non-chiral in 4D). However, in order to preserve the KK parity, one needs to impose non trivial constraints on the fixed points. In models based on an interval, one requires the Lagrangian terms localized on the two physically independent end points to be identical: obviously, this is not a direct consequence of the compactification! Moreover, the presence of explicit breaking of Lorentz invariance introduces a large arbitrariness, often neglected, in the model, because the localized interaction terms only obey to a smaller subgroup of the extra symmetries. As an example, divergences which are forbidden in the bulk emerge again via localized counter-terms. The Ultra-Violet sensitivity of the theory is generically worsened opening a Pandora box of free parameters and potentially bad ultraviolet behaviour. On the other hand, the idea of large compact extra dimensions gives opportunities for model building allowing for elegant uses of fundamental symmetries, like in gauge-Higgs unification models [6], where the freedom to add localized terms is welcome in order to obtain a realistic model.

For those reasons, we will require that Lorentz invariance is only broken globally by the compactification, and a KK parity is part of the orbifold, therefore exact and inevitable. In this spirit, the dark matter candidate is truly a remnant of Lorentz invariance, which we shall call by abuse of language, a lightest Lorentz particle (LLP) in the following. Moreover, all interactions are highly constrained, and the model will be relatively more predictive than standard KK parity models. The main hurdle to be passed is the requirement of a chiral spectrum for fermions, crucial to obtain the Standard Model in the low energy limit.

Orbifolds are quotient spaces of a manifold modulo a discrete group. The one-dimensional orbifolds are the circle $S^1 = \mathbb{R}/\mathbb{Z}$ and the interval $S^1/\mathbb{Z}_2$: the circle has neither fixed points nor chiral fermions; the interval is the only orbifold with chiral massless fermions, however it possesses two fixed points (the boundaries of the interval). If we extend our four dimensional world to include one extra dimension, therefore, there are no compactifications without boundaries which allow to obtain chiral fermions in 4D. The next step is to consider two extra dimensions. In the plane the possible isometries are translations (t), reflections, $2\pi/n$ rotations (r) with $n = 2, 3, 4, 6$ and glide-reflections (g), which are translations with a simultaneous mirror reflection. In 2D there are only 17 fundamental symmetry groups (see for example [7]) which correspond to the crystallographic groups in two dimensions, also called the wallpaper groups. The folding of the infinite periodic tiling of the plane can be described in a unique way by an orbifold. Only 3 of the resulting orbifolds are free of boundary or fixed points/lines. They are the torus $\mathbb{R}^2/\mathbf{p1}$, the Klein bottle $\mathbb{R}^2/\mathbf{pg}$ and the real projective plane $\mathbb{R}^2/\mathbf{pgg}$. Our notation refers to the fact that space groups can be defined in a purely algebraic way: instead of specifying a representation of the generators, one can list the relations among them, so we have

$$\begin{aligned}\mathbf{p1} &\simeq \mathbb{Z}^2 = \langle t_1 \rangle \times \langle t_2 \rangle, \\ \mathbf{pg} &= \langle t_2, g | [g^2, t_2] = 0, t_2 g t_2 g^{-1} = \mathbf{1} \rangle \supseteq \mathbb{Z}^2, \\ \mathbf{pgg} &= \langle r, g | r^2 = (g^2 r)^2 = \mathbf{1} \rangle \supseteq \mathbb{Z}^2, \mathbb{Z}_2.\end{aligned}$$

Only the projective plane $\mathbb{R}^2/\mathbf{pgg}$ allows chiral zero modes for fermions because it contains a π -rotation, as we will discuss in the following. We will therefore consider this geometry as the background for our model. One may push this exercise further and consider three or more extra dimensions. We will not do it in the following for the simple reason that the number of possible orbifolds increases very fast. Furthermore, adding more dimensions will lower the effective cutoff of the theory and therefore reduce the validity of the effective theory. The projective plane is the simplest possibility and the most reasonable one for building an effective theory which may have a wide validity range in energy. Here we will consider the minimal case where the Standard Model is embedded in this geometry: the only new parameter, neglecting higher order operators, is the size of the extra dimensions which determines the mass scale of the KK resonances. The geometry also contains two singular points where 4 dimensional terms can be added, and will be required as counter-terms for loop divergences: we will consider the most general such Lagrangians, with the spirit that they are small corrections (typically one loop level). This geometry was already proposed in the context of Grand Unification models [8], but no explicit example has been constructed.

2 Chiral fermions without fixed points: the real projective plane

The minimal dimension of a fermion Ψ in 6 dimensions is 8 (contrary to the 4 components in 4 and 5 D) [9]: the Clifford algebra contains 6 8×8 Gamma matrices $\Gamma^1 \dots \Gamma^6$. Moreover,

one can define

$$\Gamma^7 = \Gamma^1 \Gamma^2 \Gamma^3 \Gamma^4 \Gamma^5 \Gamma^6 \quad (2.1)$$

which allows to define two 6D chiralities via the projectors

$$P_{\pm} = \frac{1}{2} (1 \pm \Gamma^7) . \quad (2.2)$$

Therefore, the minimal spinor representation of the Lorentz group are 4-component chiral fermions $\Psi_{\pm} = P_{\pm} \Psi$. Each one of those 6D-chiral fields contains two 4D Weyl fermions of opposite 4D-chirality. In order to be more concrete, we will use the following representation for the Gamma matrices [9]:

$$\Gamma^{\mu} = \begin{pmatrix} \gamma^{\mu} & 0 \\ 0 & \gamma^{\mu} \end{pmatrix}, \quad \Gamma^5 = \begin{pmatrix} 0 & i\gamma^5 \\ i\gamma^5 & 0 \end{pmatrix}, \quad \Gamma^6 = \begin{pmatrix} 0 & \gamma^5 \\ -\gamma^5 & 0 \end{pmatrix}; \quad (2.3)$$

and consequently

$$\Gamma^7 = \begin{pmatrix} -\gamma^5 & 0 \\ 0 & \gamma^5 \end{pmatrix}, \quad \text{and} \quad P_{\pm} = \begin{pmatrix} \frac{1}{2}(1 \mp \gamma^5) & 0 \\ 0 & \frac{1}{2}(1 \pm \gamma^5) \end{pmatrix} = \begin{pmatrix} P_{L/R} & 0 \\ 0 & P_{R/L} \end{pmatrix}, \quad (2.4)$$

where P_L and P_R are the projectors on the 4D chiralities. In this basis, the 6D-chiral fermions can be written as (using the Weyl representation for the 4D Gamma matrices)

$$\Psi_+ = \begin{pmatrix} \psi_{L+} \\ \psi_{R+} \end{pmatrix}, \quad \Psi_- = \begin{pmatrix} \psi_{R-} \\ \psi_{L-} \end{pmatrix}, \quad (2.5)$$

with

$$\psi_{L\pm} = \begin{pmatrix} \chi_{\pm} \\ 0 \end{pmatrix}, \quad \psi_{R\pm} = \begin{pmatrix} 0 \\ \bar{\eta}_{\pm} \end{pmatrix}, \quad (2.6)$$

where ψ are Dirac spinors, χ and η are Weyl spinors.

The 6D action for a massless 6D-chiral fermion is

$$\begin{aligned} S_{\pm} &= \int dx_5 \int dx_6 \frac{i}{2} \left\{ \bar{\Psi}_{\pm} \Gamma^{\alpha} \partial_{\alpha} \Psi_{\pm} - (\partial_{\alpha} \bar{\Psi}_{\pm}) \Gamma^{\alpha} \Psi_{\pm} \right\} = \\ &= \int dx_5 \int dx_6 \left\{ i \bar{\psi}_{L\pm} \gamma^{\mu} \partial_{\mu} \psi_{L\pm} + i \bar{\psi}_{R\pm} \gamma^{\mu} \partial_{\mu} \psi_{R\pm} + \right. \\ &\quad \left. + \frac{1}{2} [\bar{\psi}_{L\pm} \gamma_5 (\partial_5 \mp i \partial_6) \psi_{R\pm} + \bar{\psi}_{R\pm} \gamma_5 (\partial_5 \pm i \partial_6) \psi_{L\pm} + h.c.] \right\}; \end{aligned} \quad (2.7)$$

and a mass term

$$\begin{aligned} S_{\text{mass}} &= \int dx_5 \int dx_6 M \left\{ \bar{\Psi}_+ \Psi_- + \bar{\Psi}_- \Psi_+ \right\} \\ &= \int dx_5 \int dx_6 M \left\{ \bar{\psi}_{L+} \psi_{R-} + \bar{\psi}_{R+} \psi_{L-} + h.c. \right\}. \end{aligned} \quad (2.8)$$

The only difference between the two 6D-chiralities is a different sign in front of the x_6 derivative. This feature will be important when discussing the parity properties of such fields.

The real projective plane can be defined by a π -rotation r and a glide g , whose action on the coordinates is

$$r : \begin{cases} x_5 \sim -x_5 \\ x_6 \sim -x_6 \end{cases}, \quad g : \begin{cases} x_5 \sim x_5 + \pi R_5 \\ x_6 \sim -x_6 + \pi R_6 \end{cases}. \quad (2.9)$$

Note that $r^2 = (g^2 r)^2 = 1$; for any field, the allowed parities are therefore

$$p_r = \pm 1; \quad p_g = \pm 1. \quad (2.10)$$

In terms of r and g one can define two translations:

$$t_5 = g^2 : \begin{cases} x_5 \sim x_5 + 2\pi R_5 \\ x_6 \sim x_6 \end{cases}, \quad t_6 = (gr)^2 : \begin{cases} x_5 \sim x_5 \\ x_6 \sim x_6 + 2\pi R_6 \end{cases}. \quad (2.11)$$

No Scherk-Schwarz phases can be defined on this geometry: all the fields are periodic. Note also that we can define another glide

$$g' = gr : \begin{cases} x_5 \sim -x_5 + \pi R_5 \\ x_6 \sim x_6 + \pi R_6 \end{cases}, \quad (2.12)$$

under which the fields have parity $p_{g'} = p_g p_r$. The two radii R_5 and R_6 are in principle different: here for simplicity we will fix $R_5 = R_6 = R$, and assume $R = 1$ in all the formulas, except introducing it back when discussing the phenomenology of the model. The size of the radius will determine the overall mass scale for the KK modes, $m_{KK} = 1/R$.

Let us now discuss the 4D chirality of the fermions. The glide g changes the sign of one coordinate only, x_6 : in order to keep the action invariant, from eq. 2.7, we see that the two 6D-chiralities are exchanged. Therefore, the glide requires to start with a non-chiral theory in 6D. Under the glide, a generic fermion transforms as:

$$\Psi(g(x)) = p_g \Gamma_g \Psi(x), \quad \Gamma_g = \Gamma^6 \Gamma^7. \quad (2.13)$$

The two 6D chiralities are exchanged up to a sign, therefore for both parities a non-chiral 4D massless mode is allowed. For this reason the Klein bottle, defined by a glide and a translation, does not allow for chiral fermions.

Under the rotation r both extra coordinates change sign, therefore the two 4D chiralities must have opposite parity: a zero mode is allowed only for one of the two 4D chiralities. A generic fermion transforms as:

$$\Psi(r(x)) = p_r \Gamma_r \Psi(x), \quad \Gamma_r = i \Gamma^5 \Gamma^6 \Gamma^7; \quad (2.14)$$

with this definition, $p_r = +1$ corresponds to a left-handed zero mode and $p_r = -1$ to a right-handed one. Because of eq. 2.10, for each bulk fermion there is a massless chiral

Figure 1: Fundamental domain for a torus (left) and real projective plane (right).

fermion. The real projective plane is therefore the unique 6D orbifold which allows for chiral fermions without fixed points. Note also that a bulk mass term is odd under the rotation. For completeness, the action of the second glide g' on a fermion is defined by:

$$\Psi(g'(x)) = p_g p_r \Gamma_{gr} \Psi(x), \quad \Gamma_{gr} = i\Gamma^5. \quad (2.15)$$

Note finally that the presence of a massless mode for each bulk fermion implies that supersymmetry cannot be completely broken in this background: in fact, the supersymmetry generator, which is a 6D spinor, obeys the same properties, and therefore an unbroken $N=1$ supersymmetry always survives.

2.1 KK parities and singularities on the real projective plane

The real projective plane is non-orientable and has no boundaries, however there are two points with conical singularities, where localized counter-terms can be added in general. Nevertheless, a KK parity is still preserved without any further assumption. Two symmetries can be used to define the orbifold, for example a rotation and a glide. The rotation has 4 un-equivalent fixed points: $(0, 0)$, (π, π) , $(0, \pi)$ and $(\pi, 0)$ (see figure 1). The glide, however, transforms $(0, 0) \rightarrow (\pi, \pi)$ and $(0, \pi) \rightarrow (\pi, 0)$ (and viceversa); therefore, no fixed point is present globally, and the eventual localized interactions on the corners of the fundamental square must be identified in pairs. The identification is not a consequence of an ad-hoc global symmetry acting on the UV completion of the model, as it happens in other orbifolds, like the chiral square [5], but it is part of the orbifold itself: the two identified points are indeed the same point in the 6D space. A crucial consequence is that a discrete KK parity is left unbroken: it can be identified with a translation by (π, π) (combined with r , this is equivalent to a π -rotation around the center of the square $(\pi/2, \pi/2)$, thus it is exactly the same KK parity as in [5]):

$$p_{KK} : \begin{cases} x_5 \sim x_5 + \pi \\ x_6 \sim x_6 + \pi \end{cases}. \quad (2.16)$$

Under this transformation, two identified singular points are transformed one into the other, and a generic KK mode with momentum (k, l) along the extra directions will acquire a phase $(-1)^{k+l}$: therefore, $(1, 0)$ and $(0, 1)$ identify the lightest tiers of odd particles thus containing a stable Dark Matter candidate, while the $(1, 1)$ modes can generically decay into zero modes via localized interactions. Note that the theory also possesses another KK parity

$$p'_{KK} : \begin{cases} x_5 \sim x_5 + \pi \\ x_6 \sim x_6 \end{cases}, \quad (2.17)$$

under which the $(1, 1)$ states would be odd and therefore stable. If p'_{KK} is unbroken, the two tiers $(1, 0)$ and $(0, 1)$ would also pick different parity, and therefore contain two independent candidates. However, this symmetry requires that the localized interactions on the two points are the same: this is true for terms induced by loops of bulk interactions, however a generic UV completion of the model would violate such symmetry. Not being a fundamental symmetry of the orbifold, we will discard it and assume that it is generally broken.

3 The Standard Model on the real projective plane

Here we will consider a simple extension of the Standard Model on the real projective plane, and study the spectrum of the KK modes. More complicated constructions are in principle possible, and we reserve to study them in future publications. For now we will study the SM gauge group $SU(3)_c \times SU(2)_W \times U(1)_Y$ with a single Higgs scalar doublet, and a 6D fermion for each chiral SM fermion (doublets Q and L , singlets U , D , E and possibly the singlet neutrino N). The lowest order Lagrangian will be the SM one, extended to 6 dimensions. As we will shortly see, to each SM fields it corresponds a tower of massive resonances organized in tiers of modes, labeled by two integers (l, k) which correspond to the discretized momenta along the extra directions, and the field content of each tier will crucially depend on the parities of the fields under the orbifold projection. At leading order, all the states in each tier are degenerate with mass determined by the two integers

$$m_{l,k}^2 = \frac{l^2}{R_5^2} + \frac{k^2}{R_6^2}. \quad (3.1)$$

Splittings within the modes in each tier can be generated by three mechanisms: the Higgs vacuum expectation value (VEV), bulk interaction loop corrections and higher order operators localized on the singular points. Here we will focus on the simplest case, where, due to the flatness of the metric along the extra coordinates, the Higgs VEV is constant: an important consequence is that, due to the orthogonality of wave functions of KK modes from different tiers, the Higgs mechanism will not mix the tiers. Therefore, the KK expansion remains valid and the masses will be shifted, independently on the spin of the field, by the SM mass m_0 , according to the formula: $m_{l,k}^2 = l^2 + k^2 + m_0^2$. On the other hand, the loop corrections do generate level-mixings: being small effects, for the spectrum we will limit ourselves to the leading corrections, therefore diagonal terms only. Note also that the

loop induced terms will respect the full global symmetries of the space, and therefore, as an example, no splitting and/or mixing between the $(1, 0)$ and $(0, 1)$ levels will be induced, neither decays of the $(1, 1)$ modes into SM particles. Localized terms are generally required as counter-terms for the loop divergences: however, they must respect less symmetries than the bulk loops. The only unbroken symmetry will be the KK parity p_{KK} . In the following we will assume that localized terms are small as they are required at one loop level, and we will limit ourselves to a leading order expansion in them.

In this section, we will first study the tree level spectrum for generic scalars, gauge fields and fermions on the real projective plane, thus identifying the possible field content of each tier, and then include the effect of the Higgs mechanism and lowest order localized terms on SM fields. One loops results for the lightest tier will also be presented because they play a crucial role when discussing the Dark Matter relic abundance.

3.1 Scalars

The action for a scalar field Φ is (omitting the integral along the un-compact 4 dimensions)

$$S_{\text{scalar}} = \int_0^{2\pi} dx_5 dx_6 \left\{ \partial_\alpha \Phi^\dagger \partial^\alpha \Phi - M^2 \Phi^\dagger \Phi \right\}, \quad (3.2)$$

$\alpha = 1, \dots, 6$; which leads to the equation of motion (EOM)

$$(\partial_5^2 + \partial_6^2 + p^2 - M^2) \Phi = 0, \quad (3.3)$$

where $p^2 = -\partial_\mu \partial^\mu$. After Fourier transforming along the two extra coordinates, the field can be expanded in a sum of KK modes, whose wave functions satisfy the above equation with p^2 replaced by the mass square of the mode. The solutions of this equation are usual combinations of sines and cosines (with frequencies determined by the periodicity at 2π). The wave functions can be labelled with the parities under the rotation and glide:

	p_r	p_g	spectrum
$\cos kx_5 \cos lx_6$	+	$(-1)^{k+l}$	$k, l \geq 0$
$\sin kx_5 \sin lx_6$	+	$(-1)^{k+l+1}$	$k, l > 0$
$\sin kx_5 \cos lx_6$	-	$(-1)^{k+l}$	$k > 0, l \geq 0$
$\cos kx_5 \sin lx_6$	-	$(-1)^{k+l+1}$	$k \geq 0, l > 0$

The masses are given by the formula

$$m_{k,l}^2 = M^2 + k^2 + l^2. \quad (3.4)$$

The mass eigenstates can be labeled by their parity assignment (p_r, p_g) and KK number (k, l) . Here is a full classification of the modes (with normalized wave functions):

(k, l)	p_{KK}	$(++)$	$(+-)$	$(-+)$	$(--)$
$(0, 0)$	+	$\frac{1}{2\pi}$			
$(0, 2l)$	+	$\frac{1}{\sqrt{2\pi}} \cos 2lx_6$			$\frac{1}{\sqrt{2\pi}} \sin 2lx_6$
$(0, 2l-1)$	-		$\frac{1}{\sqrt{2\pi}} \cos(2l-1)x_6$	$\frac{1}{\sqrt{2\pi}} \sin(2l-1)x_6$	
$(2k, 0)$	+	$\frac{1}{\sqrt{2\pi}} \cos 2kx_5$		$\frac{1}{\sqrt{2\pi}} \sin 2kx_5$	
$(2k-1, 0)$	-		$\frac{1}{\sqrt{2\pi}} \cos(2k-1)x_5$		$\frac{1}{\sqrt{2\pi}} \sin(2k-1)x_5$
$(k, l)_{k+l \text{ even}}$	+	$\frac{1}{\pi} \cos kx_5 \cos lx_6$	$\frac{1}{\pi} \sin kx_5 \sin lx_6$	$\frac{1}{\pi} \sin kx_5 \cos lx_6$	$\frac{1}{\pi} \cos kx_5 \sin lx_6$
$(k, l)_{k+l \text{ odd}}$	-	$\frac{1}{\pi} \sin kx_5 \sin lx_6$	$\frac{1}{\pi} \cos kx_5 \cos lx_6$	$\frac{1}{\pi} \cos kx_5 \sin lx_6$	$\frac{1}{\pi} \sin kx_5 \cos lx_6$

3.2 Gauge fields

The action for an abelian gauge field is (also valid at quadratic level for non-abelian gauge symmetries)

$$S_{\text{gauge}} = \int_0^{2\pi} dx_5 dx_6 \left\{ -\frac{1}{4} F_{\alpha\beta} F^{\alpha\beta} - \frac{1}{2\xi} (\partial_\mu A^\mu - \xi(\partial_5 A_5 + \partial_6 A_6))^2 \right\}, \quad (3.5)$$

where $F_{\alpha\beta} = \partial_\alpha A_\beta - \partial_\beta A_\alpha$, and the ξ -gauge fixing term is added to eliminate the mixing between A_μ and the extra polarizations A_5 and A_6 . The equation of motion for the vector component is

$$-\partial^\mu F_{\mu\nu} - \frac{1}{\xi} \partial_\nu \partial^\mu A_\mu + (\partial_5^2 + \partial_6^2) A_\nu = (p^2 + \partial_5^2 + \partial_6^2) A_\nu = 0, \quad (3.6)$$

which is the same as for a scalar field, and we have assumed that each KK mode satisfies the usual 4D equation in ξ -gauge:

$$-\partial^\mu F_{\mu\nu} - \frac{1}{\xi} \partial_\nu \partial^\mu A_\mu = p^2 A_\nu. \quad (3.7)$$

Once the parities are assigned, the spectrum and wave functions will be the same as for the scalar field (with $M = 0$).

The A_5 - A_6 scalar sector is more complicated: in fact, the massive vector modes acquire their longitudinal polarization by eating a tower of scalar components provided by a combination of A_5 and A_6 , while another combination will give rise to a single tower of physical scalar states. Moreover, the parities of the scalar components are determined by the fact that they are part of a 6D vector, therefore if the vector component A_μ has parities (p_r, p_g) , the parities of A_5 and A_6 components are respectively $(-p_r, p_g)$ and $(-p_r, -p_g)$. In generic ξ -gauge, the EOMs are

$$-\partial_\mu^2 A_5 + \xi \partial_5 (\partial_5 A_5 + \partial_6 A_6) + \partial_6 (\partial_6 A_5 - \partial_5 A_6) = 0, \quad (3.8)$$

$$-\partial_\mu^2 A_6 + \xi \partial_6 (\partial_5 A_5 + \partial_6 A_6) + \partial_5 (\partial_5 A_6 - \partial_6 A_5) = 0. \quad (3.9)$$

Here we will focus on two gauge choices: the Unitary gauge, where all non-physical degrees of freedom are removed, and the Feynman-'t Hooft gauge, which is more useful for loop calculations.

Feynman-'t Hooft gauge

In the Feynman-'t Hooft gauge $\xi = 1$, the equations of motion for A_5 and A_6 decouple:

$$(\partial_5^2 + \partial_6^2 - \partial_\mu^2)A_{5,6} = 0, \quad (3.10)$$

therefore the two components can be treated as two independent scalar fields with proper parities. The wave functions and masses are the same as in the scalar case presented in detail in Section 3.1.

Unitary gauge

In the unitary gauge $\xi \rightarrow \infty$, the combination

$$\partial_5 A_5 + \partial_6 A_6 = 0. \quad (3.11)$$

The two fields are not independent, and one can therefore expand both fields on the same tower of 4D scalars $A_{(k,l)}$:

$$A_5 = \sum \phi_5(x_5, x_6) A_{(k,l)}, \quad A_6 = \sum \phi_6(x_5, x_6) A_{(k,l)}, \quad (3.12)$$

with $\partial_5 \phi_5 + \partial_6 \phi_6 = 0$. Using the latter relation in eq.s (3.8–3.9), the two wave functions respect the usual EOM of a scalar field:

$$(p^2 + \partial_5^2 + \partial_6^2)\phi_{5/6} = 0; \quad (3.13)$$

spectra and wave functions are again the same as in the scalar case, with the additional constraint from eq. 3.11. In the following tables, we list in detail the masses and normalized wave functions for the 4 possible parity assignments. In the $(++)$ case the gauge symmetry is unbroken:

(k, l)	p_{KK}	$A_\mu^{(++)}$	$A_5^{(-+)}$	$A_6^{(--)}$
$(0, 0)$	+	$\frac{1}{2\pi}$		
$(0, 2l)$	+	$\frac{1}{\sqrt{2\pi}} \cos 2lx_6$		
$(0, 2l - 1)$	−		$\frac{1}{\sqrt{2\pi}} \sin(2l - 1)x_6$	
$(2k, 0)$	+	$\frac{1}{\sqrt{2\pi}} \cos 2kx_5$		
$(2k - 1, 0)$	−			$\frac{1}{\sqrt{2\pi}} \sin(2k - 1)x_5$
$(k, l)_{k+l \text{ even}}$	+	$\frac{1}{\pi} \cos kx_5 \cos lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \sin kx_5 \cos lx_6$	$-\frac{k}{\pi\sqrt{k^2+l^2}} \cos kx_5 \sin lx_6$
$(k, l)_{k+l \text{ odd}}$	−	$\frac{1}{\pi} \sin kx_5 \sin lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \cos kx_5 \sin lx_6$	$-\frac{k}{\pi\sqrt{k^2+l^2}} \sin kx_5 \cos lx_6$

If the gauge symmetry is broken by the glide(s), case $(+-)$, there is no zero mode in the spectrum:

(k, l)	p_{KK}	$A_\mu^{(+-)}$	$A_5^{(--)}$	$A_6^{(-+)}$
$(0, 0)$	+			
$(0, 2l)$	+		$\frac{1}{\sqrt{2\pi}} \sin 2lx_6$	
$(0, 2l - 1)$	-	$\frac{1}{\sqrt{2\pi}} \cos(2l - 1)x_6$		
$(2k, 0)$	+			$\frac{1}{\sqrt{2\pi}} \sin 2kx_5$
$(2k - 1, 0)$	-	$\frac{1}{\sqrt{2\pi}} \cos(2k - 1)x_5$		
$(k, l)_{k+l \text{ even}}$	+	$\frac{1}{\pi} \sin kx_5 \sin lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \cos kx_5 \sin lx_6$	$-\frac{k}{\pi\sqrt{k^2+l^2}} \sin kx_5 \cos lx_6$
$(k, l)_{k+l \text{ odd}}$	-	$\frac{1}{\pi} \cos kx_5 \cos lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \sin kx_5 \cos lx_6$	$-\frac{k}{\pi\sqrt{k^2+l^2}} \cos kx_5 \sin lx_6$

If the gauge symmetry is broken by the rotation (and the glide g'), then there is a zero mode living in the A_5 component:

(k, l)	p_{KK}	$A_\mu^{(-+)}$	$A_5^{(++)}$	$A_6^{(+-)}$
$(0, 0)$	+		$\frac{1}{2\pi}$	
$(0, 2l)$	+		$\frac{1}{\sqrt{2\pi}} \cos 2lx_6$	
$(0, 2l - 1)$	-	$\frac{1}{\sqrt{2\pi}} \sin(2l - 1)x_6$		
$(2k, 0)$	+	$\frac{1}{\sqrt{2\pi}} \sin 2kx_5$		
$(2k - 1, 0)$	-			$\frac{1}{\sqrt{2\pi}} \cos(2k - 1)x_5$
$(k, l)_{k+l \text{ even}}$	+	$\frac{1}{\pi} \sin kx_5 \cos lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \cos kx_5 \cos lx_6$	$\frac{k}{\pi\sqrt{k^2+l^2}} \sin kx_5 \sin lx_6$
$(k, l)_{k+l \text{ odd}}$	-	$\frac{1}{\pi} \cos kx_5 \sin lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \sin kx_5 \sin lx_6$	$\frac{k}{\pi\sqrt{k^2+l^2}} \cos kx_5 \cos lx_6$

Finally, the gauge symmetry can be broken by both rotation and glide g ; in this case the zero modes resides in A_6 :

(k, l)	p_{KK}	$A_\mu^{(--)}$	$A_5^{(+-)}$	$A_6^{(++)}$
$(0, 0)$	+			$\frac{1}{2\pi}$
$(0, 2l)$	+	$\frac{1}{\sqrt{2\pi}} \sin 2lx_6$		
$(0, 2l - 1)$	-		$\frac{1}{\sqrt{2\pi}} \cos(2l - 1)x_6$	
$(2k, 0)$	+			$\frac{1}{\sqrt{2\pi}} \cos 2kx_5$
$(2k - 1, 0)$	-	$\frac{1}{\sqrt{2\pi}} \sin(2k - 1)x_5$		
$(k, l)_{k+l \text{ even}}$	+	$\frac{1}{\pi} \cos kx_5 \sin lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \sin kx_5 \sin lx_6$	$\frac{k}{\pi\sqrt{k^2+l^2}} \cos kx_5 \cos lx_6$
$(k, l)_{k+l \text{ odd}}$	-	$\frac{1}{\pi} \sin kx_5 \cos lx_6$	$\frac{l}{\pi\sqrt{k^2+l^2}} \cos kx_5 \cos lx_6$	$\frac{k}{\pi\sqrt{k^2+l^2}} \sin kx_5 \sin lx_6$

3.3 Fermions

The action for a 6D Dirac fermion in Section 2 leads to the following EOMs for the 4 components:

$$i\bar{\sigma}^\mu \partial_\mu \chi_\pm + (\partial_5 \mp i\partial_6) \bar{\eta}_\pm = 0, \quad (3.14)$$

$$i\sigma^\mu \partial_\mu \bar{\eta}_\pm - (\partial_5 \pm i\partial_6) \chi_\pm = 0; \quad (3.15)$$

as usual, we expand each component in a tower of 4D Dirac fermions $f_{l,r}$ (the subscript l, r indicate the 4D chirality) satisfying the usual Dirac EOMs. Those first order equations can

be decoupled [10], and each component satisfies the same quadratic equation as the scalar field in the previous section. The solutions are usual combinations of sin and cos, and the first order EOMs relate the coefficients of the two 4D components. The exact form of the solutions will be determined by the parity assignments of the fields. The rotation gives a different parity to the two 4D-chiralities, and a fermion with $p_r = +$ ($p_r = -$) will have a left-handed (right-handed) zero mode. On the other hand, the glide will relate the two 6D chiralities, so that the four wave functions are not independent: the value of the parity under the glide does not play any role on the zero mode spectrum and, as we will see, the only requirement is that the SM doublets and singlets have the same glide parity in order to allow Yukawa couplings with the bulk Higgs.

For a left-handed fermion, case $(+\pm)$, the KK modes are given by:

(k, l)	χ_+	χ_-	$\bar{\eta}_+$	$\bar{\eta}_-$
$(0, 0)$	$\frac{1}{2\sqrt{2\pi}}$	$\pm \frac{1}{2\sqrt{2\pi}}$	0	0
$(0, l)$	$\frac{1}{2\pi} \cos lx_6$	$\pm(-1)^l \frac{1}{2\pi} \cos lx_6$	$-\frac{i}{2\pi} \sin lx_6$	$\pm(-1)^l \frac{i}{2\pi} \sin lx_6$
$(k, 0)$	$\frac{1}{2\pi} \cos kx_5$	$\pm(-1)^k \frac{1}{2\pi} \cos kx_5$	$-\frac{1}{2\pi} \sin kx_5$	$\mp(-1)^k \frac{1}{2\pi} \sin kx_5$

while for both $k, l \neq 0$, there are 2 degenerate solutions for each level which can be parameterized as

$$\Psi^{(+\pm)} = \begin{pmatrix} (a \cos kx_5 \cos lx_6 + b \sin kx_5 \sin lx_6) f_l \\ \pm(-1)^{k+l} (c \sin kx_5 \cos lx_6 - d \cos kx_5 \sin lx_6) \bar{f}_r \\ \pm(-1)^{k+l} (a \cos kx_5 \cos lx_6 - b \sin kx_5 \sin lx_6) f_l \\ (c \sin kx_5 \cos lx_6 + d \cos kx_5 \sin lx_6) \bar{f}_r \end{pmatrix}, \quad (3.16)$$

where we can use the EOMs and normalization condition to fix the coefficients

$$\begin{aligned} a &= \frac{\cos \alpha}{\sqrt{2\pi}} & c &= -\frac{k \cos \alpha - il \sin \alpha}{\sqrt{2\pi} \sqrt{k^2 + l^2}} \\ b &= \frac{\sin \alpha}{\sqrt{2\pi}} & d &= \frac{k \sin \alpha - il \cos \alpha}{\sqrt{2\pi} \sqrt{k^2 + l^2}} \end{aligned} \quad (3.17)$$

The two orthogonal states can be obtained by choosing $\alpha = \theta$ and $\alpha = \pi/2 + \theta$, where θ is an arbitrary mixing angle.

For a right-handed fermion, case $(-\pm)$:

(k, l)	χ_+	χ_-	$\bar{\eta}_+$	$\bar{\eta}_-$
$(0, 0)$	0	0	$\frac{1}{2\sqrt{2\pi}}$	$\pm \frac{1}{2\sqrt{2\pi}}$
$(0, l)$	$-\frac{i}{2\pi} \sin lx_6$	$\pm(-1)^l \frac{i}{2\pi} \sin lx_6$	$\frac{1}{2\pi} \cos lx_6$	$\pm(-1)^l \frac{1}{2\pi} \cos lx_6$
$(k, 0)$	$\frac{1}{2\pi} \sin kx_5$	$\pm(-1)^k \frac{1}{2\pi} \sin kx_5$	$\frac{1}{2\pi} \cos kx_5$	$\pm(-1)^k \frac{1}{2\pi} \cos kx_5$

and, for $k, l \neq 0$:

$$\Psi^{(-g)} = \begin{pmatrix} (a \sin kx_5 \cos lx_6 + b \cos kx_5 \sin lx_6) f_l \\ \pm(-1)^{k+l} (c \cos kx_5 \cos lx_6 - d \sin kx_5 \sin lx_6) \bar{f}_r \\ \pm(-1)^{k+l} (a \sin kx_5 \cos lx_6 - b \cos kx_5 \sin lx_6) f_l \\ (c \cos kx_5 \cos lx_6 + d \sin kx_5 \sin lx_6) \bar{f}_r \end{pmatrix}, \quad (3.18)$$

with

$$\begin{aligned} c &= \frac{\cos \alpha}{\sqrt{2\pi}} & a &= \frac{k \cos \alpha + i l \sin \alpha}{\sqrt{2\pi} \sqrt{k^2 + l^2}} \\ d &= \frac{\sin \alpha}{\sqrt{2\pi}} & b &= -\frac{k \sin \alpha + i l \cos \alpha}{\sqrt{2\pi} \sqrt{k^2 + l^2}} \end{aligned} \quad (3.19)$$

Note that we have fixed the normalization of the wave functions in such a way that the mass of each (k, l) KK level is real, i.e. $m_{(k,l)} = \sqrt{k^2 + l^2}$.

3.4 6D loop corrections

The degeneracy of each KK level is removed at loop level: a complete calculation of the shifts is however beyond the scope of this paper. In the following we will focus on the modes $(n, 0)$ and $(0, n)$ with n odd, in fact this case covers the lightest tiers, and the result will be important in the next section to determine the nature of the Dark Matter candidate and estimate its relic abundance. In general, the loop contributions (that we generically label Π) can be divided in 4 pieces

$$\Pi = \Pi_T + p_g \Pi_G + p_g p_r \Pi_{G'} + p_r \Pi_R : \quad (3.20)$$

the first term Π_T is the contribution one would get from the same fields on a torus and, after renormalization of the bulk kinetic terms, it leaves a finite contribution. The other three terms correspond to the two glides and rotation, in the sense that their sign depends on the parities (p_r, p_g) of the fields running in the loop. The contribution of the two glides is finite because the glides do not have any fixed points where a counter-term could be localized. On the other hand, the rotation does generate divergences which can be cut-off by counter-terms localized on the four points left fixed by the rotation, i.e. the two singular points of the orbifold. The singularities will be equally spread on the two points, because of the extended global symmetries of the bulk interactions. In the next section we will discuss the generic structure of the counter-terms: for now we will limit ourselves to cutting off the momentum integral in the loop and compute the coefficient on the log divergent term. Note also that bulk interactions respect both p_{KK} and p'_{KK} , therefore there will be no mixing between the states $(n, 0)$ and $(0, n)$: in the following we will compute the diagonal corrections, as the off diagonal ones do generate sub-leading corrections to the spectrum.

3.4.1 Gauge bosons

The tiers under study contain a gauge-scalar for each SM gauge bosons. For a generic gauge group, the mass receives corrections from the diagrams listed in Fig. 2. We performed the calculation in 3 different ways: we employed a novel method consisting in expanding in KK modes only along one direction and using the resummed 5D propagator [11] in the sum, and we checked the result, when possible, using the expansions in winding modes [12] and in 6D KK modes [13]. The methods are summarized in Appendix A, where we explicitly detail the three methods in the computation of the scalar loop “f” in the figure. The result of the calculation is summarized in the following table:

Figure 2: One-loop radiative corrections to the gauge scalar self-energy: gauge (a–c), ghost (d), fermion (e) and scalar (f–g) loops.

δm^2 gauge scalars		$\times p_g$	$\times p_g p_r$	$\times p_r$
a	$5T_6$	$5 \cdot 7\zeta(3)$	$3 \cdot (7\zeta(3) + B_1(n))$	$3n^2\pi^2 L$
b	0	0	$-12B_2(n)$	0
c	$-T_6$	$-3 \cdot 7\zeta(3)$	$-(7\zeta(3) + B_3(n))$	$5n^2\pi^2 L$
d	0	0	$-2B_2(n)$	0
e	$-8T_6$	0	0	0
f	T_6	$7\zeta(3)$	$(7\zeta(3) + B_1(n))$	$n^2\pi^2 L$
g	0	0	$-4B_2(n)$	0

The contributions in the table must be multiplied by a normalization factor $\frac{1}{4} \frac{g^2 C(r)}{16\pi^4 R^2}$, where $g = \frac{g_6}{2\pi R}$ is the effective 4D gauge coupling and $C(r)$ is a gauge group factor (defined as $\text{Tr}(t_r^a t_r^b) = C(r)\delta^{a,b}$ for a field in the representation r of a non-abelian group running in the loop, and the charge squared for a U(1)). In the formula, T_6 is the typical sum appearing in the torus compactification [13]

$$T_6 = \frac{1}{\pi} \sum_{(k,l) \neq (0,0)} \frac{1}{(k^2 + l^2)^2} \sim 1.92, \quad (3.21)$$

$L = \log \frac{\Lambda^2 + n^2}{n^2}$ is the log divergence associated with the rotation, and the n -dependent contributions $B_{1,2,3}$ are small corrections listed in the Appendix B and coming from heavier modes

running in the loop. Summing over the SM fields, the corrections are:

$$\delta m_B^2 = \frac{g'^2}{64\pi^4 R^2} [-79T_6 + 14\zeta(3) + \pi^2 n^2 L + B_1 - 4B_2] , \quad (3.22)$$

$$\delta m_W^2 = \frac{g^2}{64\pi^4 R^2} [-39T_6 + 70\zeta(3) + 17\pi^2 n^2 L + 7B_1 - 32B_2 - 2B_3] , \quad (3.23)$$

$$\delta m_G^2 = \frac{g_s^2}{64\pi^4 R^2} [-36T_6 + 84\zeta(3) + 24\pi^2 n^2 L + 9B_1 - 42B_2 - 3B_3] . \quad (3.24)$$

Numerically, for $n=1$, the corrections to the mass $\delta m = \frac{1}{2} \frac{\delta m^2}{m}$ are:

$$\delta m_B R = (-1.4 + 0.1L) \cdot 10^{-3} = -0.00094 , \quad (3.25)$$

$$\delta m_W R = (-0.4 + 5.8L) \cdot 10^{-3} = 0.026 , \quad (3.26)$$

$$\delta m_G R = (+0.2 + 28L) \cdot 10^{-3} = 0.13 ; \quad (3.27)$$

where we use $\alpha_s(M_Z) = 0.118$, $\alpha(M_Z) = 1/127$, $\sin^2 \theta_W = 0.23$ and $\Lambda = 10$ ($L = 4.6$).

3.4.2 Fermions

The corrections to the fermionic Lagrangian for a generic KK mode can be written in general as:

$$\delta \mathcal{L} = a_L \bar{\psi} \gamma^\mu p_\mu P_L \psi + a_R \bar{\psi} \gamma^\mu p_\mu P_R \psi - b \bar{\psi} \psi . \quad (3.28)$$

The wave function renormalizations (in general different for the left-handed and the right-handed components) can be re-absorbed by a field renormalization, so that the shift in the mass (at leading order in the corrections) is:

$$\delta m_F = b - m_n \frac{a_L + a_R}{2} . \quad (3.29)$$

In the following we will list the contribution of the gauge and scalar (Higgs) loops to the three terms, in units of $\frac{1}{4} \frac{g^2 C_2(r)}{16\pi^4 R}$ for the gauge loops (where $C_2(r) = (N^2 - 1)/2N$ for a fundamental of $SU(N)$, and the charge squared for a $U(1)$) and $\frac{1}{4} \frac{y^2}{16\pi^4 R}$ for the Higgs (where y is the effective Yukawa coupling), to be multiplied by the parity of the bosonic field in the loop:

fermions		$\times p_g$	$\times p_g p_r$	$\times p_r$
$n^2 a_L$ gauge	0	$2 \cdot 7\zeta(3)$	$2 \cdot (-7\zeta(3) + F_1(n) + F_2(n))$	0
$n^2 a_R$ gauge	0	$2 \cdot 7\zeta(3)$	$-2F_2(n)$	0
$n^2 b$ gauge	0	$4n \cdot 7\zeta(3)$	$-6nF_2(n)$	$4n^3 \pi^2 L$
$n^2 a_L$ scalar	0	$7\zeta(3)$	$-7\zeta(3) + F_1(n) + F_2(n)$	$n^2 \pi^2 L$
$n^2 a_R$ scalar	0	$7\zeta(3)$	$-F_2(n)$	0
$n^2 b$ scalar	0	$2n \cdot 7\zeta(3)$	$-nF_2(n)$	$n^3 \pi^2 L$

The n -dependent terms are listed in Appendix B. For a generic fermion in the fundamental representation of SU(2) weak and SU(3) color and with hypercharge Y_F :

$$\delta m_F = \frac{1}{64\pi^2 R n} \left\{ (21\zeta(3) + 4n^2\pi^2 L - F_1 - 6F_2) \left(Y_F^2 g'^2 + \frac{3}{4}g^2 + \frac{4}{3}g_s^2 \right) + \frac{1}{2} (21\zeta(3) + n^2\pi^2 L - F_1 - 2F_2) y_F^2 \right\} . \quad (3.30)$$

Numerically, at level $n = 1$, for each SM fermion we find:

$\delta m_F R$	Q	U	D	L	E	N
light gen.s	0.075	0.067	0.065	0.012	0.004	0
third gen	0.081	0.072	0.065	0.012	0.004	0

where we used the same numerical inputs as for the bosons, and $y_{top} = 1$.

3.5 Localized operators

The divergences corresponding to the rotation require the presence of counter-terms localized on the two singular points. Due to the symmetries of the bulk interactions, the counter-terms should be equal. However, here we will take a more general approach, and add different terms on the two singularities: in this way we will break all additional global symmetries. In order to leave glide-invariance explicit, we define two localization operators:

$$\delta_0 = \frac{1}{2} (\delta(x_5)\delta(x_6) + \delta(x_5 - \pi)\delta(x_6 - \pi)) , \quad (3.31)$$

$$\delta_\pi = \frac{1}{2} (\delta(x_5)\delta(x_6 - \pi) + \delta(x_5 - \pi)\delta(x_6)) , \quad (3.32)$$

and label the two singular points with a subscript 0 for the point $(0, 0) = (\pi, \pi)$, and π for $(0, \pi) = (\pi, 0)$.

In general the localized interactions must respect only 4-dimensional Lorentz invariance, and the residual gauge invariance. For a scalar field like the Higgs many terms can be added including a mass term: here we will neglect this case because of the many free parameters and the low phenomenological interest of the Higgs resonances in this model. For a gauge field the situation is much simpler due to gauge invariance: in order to preserve the residual gauge invariance along the extra coordinate, we will write the localized interactions in terms of stress-energy tensor components [14]:

$$\mathcal{L}_i = \frac{\delta_i}{\Lambda^2} \left(-\frac{r_{1i}}{4} F_{\mu\nu}^2 - \frac{r_{2i}}{2} F_{56}^2 + \frac{r_{5i}}{2} F_{5\mu}^2 + \frac{r_{6i}}{2} F_{6\mu}^2 + \frac{r_{56i}}{2} F_{5\mu} F_6^\mu \right) ; \quad (3.33)$$

where $i = 0, \pi$, and the cutoff suppression compensates for the dimension of the 6D fields (2 for a boson and 5/2 for a spinor). For a standard model gauge boson, with parities $(+, +)$,

notice that both $A_{5,6}$ and $\partial_{5,6}A_\mu$ vanish on the singular points, therefore $F_{5\mu} = F_{6\mu} = 0$ and $F_{56} = \partial_5 A_6 - \partial_6 A_5$:

$$\mathcal{L}_i = \frac{\delta_i}{\Lambda^2} \left(-\frac{r_{1i}}{4} F_{\mu\nu}^2 - \frac{r_{2i}}{2} (\partial_5 A_6 - \partial_6 A_5)^2 \right). \quad (3.34)$$

The first term corrects the kinetic term of the vector bosons, and it also introduces mixing between modes with different (k, l) . Here we will assume those terms to be small, of the same order as the 1-loop corrections: this is a reasonable assumptions because they are in fact counter-terms required by divergences at 1-loop and their coefficient is suppressed by the cut-off of the model. Therefore, most off-diagonal terms will give higher order corrections to the masses: this is not the case, however, for tiers that are degenerate like (k, l) and (l, k) . In fact, exchanging the two extra direction is a good symmetry of the real projective plane (this is true for $R_5 = R_6$ only, for different radii the degeneracy is removed at tree level). When expanding the localized terms in KK modes, the 2×2 blocks will have equal entries, while the loop contribution will be such that the diagonal entries are equal: from this, we see that the block can be diagonalized by the sum and difference of the two states ¹. Therefore, we define

$$(k, l)_\pm = \frac{(k, l) \pm (l, k)}{\sqrt{2}}, \quad \text{with } l > k, l, k = 0, 1, \dots \infty \quad (3.35)$$

and parameterize the correction to the kinetic term as:

$$\mathcal{Z}_{ij} = \delta_{ij} + \frac{z_{ij}}{4\pi^2 \Lambda^2}. \quad (3.36)$$

In this new basis ($r_{1\pm} = r_{10} \pm r_{1\pi}$):

z_{ij}	$(0, 0)$	$(0, 2l)_+$	$(2l, 2l)$	$(2k, 2l)_+$	$(2l - 1, 2l - 1)$	$(2k - 1, 2l - 1)_+$
$(0, 0)$	r_{1+}	$2r_{1+}$	$2r_{1+}$	$2\sqrt{2}r_{1+}$	$2r_{1-}$	$2\sqrt{2}r_{1-}$
$(0, 2l')_+$	$2r_{1+}$	$4r_{1+}$	$4r_{1+}$	$4\sqrt{2}r_{1+}$	$4r_{1-}$	$4\sqrt{2}r_{1-}$
$(2l', 2l')$	$2r_{1+}$	$4r_{1+}$	$4r_{1+}$	$4\sqrt{2}r_{1+}$	$4r_{1-}$	$4\sqrt{2}r_{1-}$
$(2k', 2l')_+$	$2\sqrt{2}r_{1+}$	$4\sqrt{2}r_{1+}$	$4\sqrt{2}r_{1+}$	$8r_{1+}$	$4\sqrt{2}r_{1-}$	$8r_{1-}$
$(2l' - 1, 2l' - 1)$	$2r_{1-}$	$4r_{1-}$	$4r_{1-}$	$4\sqrt{2}r_{1-}$	$4r_{1+}$	$4\sqrt{2}r_{1+}$
$(2k' - 1, 2l' - 1)_+$	$2\sqrt{2}r_{1-}$	$4\sqrt{2}r_{1-}$	$4\sqrt{2}r_{1-}$	$8r_{1-}$	$4\sqrt{2}r_{1+}$	$8r_{1+}$

while $(0, 2l)_-$, $(2k, 2l)_-$, $(2k - 1, 2l - 1)_-$, $(2k, 2l - 1)_\pm$ and $(2k - 1, 2l)_\pm$ (with $l > k$) are not affected. The correction to the zero mode will renormalize the gauge coupling:

$$g^2 = \frac{g_6^2}{4\pi^2} \frac{1}{1 + \frac{r_{10} + r_{1\pi}}{4\pi^2 \Lambda^2}} \sim \frac{g_6^2}{4\pi^2} \left(1 - \frac{r_{10} + r_{1\pi}}{4\pi^2 \Lambda^2} + \dots \right); \quad (3.37)$$

¹The situation is more complicated when k and l are part of a Pitagorean triple such that $k^2 + l^2 = n^2$ or quartet with $k^2 + l^2 = n^2 + m^2$: in this cases 3 or 4 states will be degenerate. However, this situation only happens for relatively large integers, the smallest ones being $(0, 5) - (3, 4)$, $(5, 5) - (1, 7)$, $(1, 8) - (4, 7)$, $(2, 9) - (6, 7)$, $(0, 10) - (6, 8)$ and so on. Therefore, the first case happens for states of mass $5\sqrt{2} \sim 7$, which is too close to the cutoff and therefore phenomenologically not interesting: for this reason we will not explore the possibility of Pitagorean triples any further.

while the diagonal entries affect the masses:

$$m_{(k,l)}^2 = \sqrt{k^2 + l^2} \left(1 - \frac{z_{(k,l)}}{4\pi^2 \Lambda^2} + \dots \right). \quad (3.38)$$

Note also that many states are not affected by the localized terms: this means that the quantum corrections to such states are finite at 1-loop.

A similar analysis can be performed for the scalar components of the gauge fields: note that no further mixing between the vector and scalars is induced, therefore the tree level bulk gauge fixing term is still appropriate. In this case, it is the $(k, l)_{\text{ev.}}$ modes to be unaffected (in Unitary gauge), and the correction is a mass term

$$\delta m_{i,j}^2 = m_i m_j \frac{\delta_{ij}}{4\pi^2 \Lambda^2}. \quad (3.39)$$

In the sum-difference basis, we obtain

δ_{ij}	$(0, 2l - 1)_+$	$(0, 2l - 1)_-$	$(2k, 2l - 1)_+$	$(2k, 2l - 1)_-$
$(0, 2l' - 1)_+$	$4r_{2\pi}$	0	0	$4\sqrt{2}r_{2\pi}$
$(0, 2l' - 1)_-$	0	$4r_{20}$	$4\sqrt{2}r_{20}$	0
$(2k', 2l' - 1)_+$	0	$4\sqrt{2}r_{20}$	$8r_{20}$	0
$(2k', 2l' - 1)_-$	$4\sqrt{2}r_{2\pi}$	0	0	$8r_{2\pi}$

This discussion can be easily extended for fermions where, due to the vanishing of one of the two 4D chiral components, no mass term can be added and only operators of dimension 6 (like in the gauge boson case) are relevant.

3.6 Electroweak symmetry breaking: the Higgs VEV

Another source of mass is the Higgs VEV: here we will assume that the Higgs is $(+, +)$ and its bulk potential contains a negative mass, so that a constant VEV is generated for the 6D Higgs scalar field. Due to the flatness of the VEV along the extra coordinates, it does not induce mixing between different KK tiers, therefore the KK expansion presented before can still be utilized to describe mass eigenstates. At the level $(0, 0)$, therefore, we obtain precisely the SM spectrum and the absence of mixing with higher modes also means that the model does not suffer from dangerous tree level corrections to precision electroweak observables like the S and T parameters. For heavy tiers, the Higgs VEV induces a mixing between the weak neutral bosons, in a similar fashion as in the SM: the mixing angle is large because the states are degenerate at tree level, and loop effects will change the value with respect to the SM Weinberg angle. In the fermion sector, only the top will be significantly affected, and the two Dirac fermions corresponding to the left and right-handed SM top will be mixed.

3.6.1 Gauge bosons: general analysis

The Higgs VEV introduces new mixing between the vectors and some scalar components that must be cancelled by a suitable gauge fixing term. For an abelian gauge group, the

gauge fixing term in eq. 3.5 is replaced by

$$\mathcal{L}_{\xi\text{-gauge}} = -\frac{1}{2\xi} (\partial_\mu A^\mu - \xi(\partial_5 A_5 + \partial_6 A_6 - g v_6 \phi_0))^2, \quad (3.40)$$

when the Higgs is expanded

$$H = \frac{1}{\sqrt{2}} (v_6 + h + i\phi_0). \quad (3.41)$$

The EOMs of the vector part are modified simply by the addition of a mass term $m_V^2 = g_6^2 v_6^2$. For the scalars $A_{5,6}$ and ϕ_0 , the new EOMs are:

$$(p^2 - m_V^2)A_5 + \partial_6(\partial_6 A_5 - \partial_5 A_6) + m_V \partial_5 \phi_0 + \xi \partial_5(\partial_5 A_5 + \partial_6 A_6 - m_V \phi_0) = 0, \quad (3.42)$$

$$(p^2 - m_V^2)A_6 + \partial_5(\partial_5 A_6 - \partial_6 A_5) + m_V \partial_6 \phi_0 + \xi \partial_6(\partial_5 A_5 + \partial_6 A_6 - m_V \phi_0) = 0, \quad (3.43)$$

$$(p^2 + \partial_5^2 + \partial_6^2)\phi_0 - m_V(\partial_5 A_5 + \partial_6 A_6) + \xi m_V(\partial_5 A_5 + \partial_6 A_6 - m_V \phi_0) = 0. \quad (3.44)$$

In the Feynman-'t Hooft gauge ($\xi = 1$), the EOMs decouple:

$$(p^2 - m_V^2 + \partial_5^2 + \partial_6^2) \begin{bmatrix} A_5 \\ A_6 \\ \phi_0 \end{bmatrix} = 0, \quad (3.45)$$

and we have three independent towers with masses $m_{(l,k)}^2 = l^2 + k^2 + m_V^2$, the only difference being the parities under rotation and glide. In the Unitary gauge, the condition

$$m_V \phi_0 = \partial_5 A_5 + \partial_6 A_6 \quad (3.46)$$

holds. Imposing this condition on the EOMs, we obtain the same decoupled equations as in the Feynman-'t Hooft gauge, however the fields are not independent anymore. Note that one solution of the constraint has the form:

$$\partial_5 A_5 + \partial_6 A_6 = 0 \quad \text{and} \quad \phi_0 = 0; \quad (3.47)$$

those solutions correspond to the physical scalars described in the previous sections, the effect of the Higgs VEV only appears in the extra mass contribution m_V^2 . The second independent combination of states which satisfies the condition is a new physical scalar, mainly consisting of Higgs component: if the gauge symmetry is unbroken by the orbifold

(k, l)	p_{KK}	$\phi_0^{(++)}$	$A_5^{(-+)}$	$A_6^{(--)}$
$(0, 0)$	+			
$(0, 2l)$	+	$\frac{2l}{\sqrt{2\pi} \sqrt{(2l)^2 + m_V^2}} \cos 2lx_6$		$\frac{m_V}{\sqrt{2\pi} \sqrt{(2l)^2 + m_V^2}} \sin 2lx_6$
$(0, 2l - 1)$	-			
$(2k, 0)$	+	$\frac{2k}{\sqrt{2\pi} \sqrt{(2k)^2 + m_V^2}} \cos 2kx_5$	$\frac{m_V}{\sqrt{2\pi} \sqrt{(2k)^2 + m_V^2}} \sin 2kx_5$	
$(2k - 1, 0)$	-

$(k, l)_{k+l \text{ odd}}$	-	$\frac{k^2 + l^2}{\pi N_{k,l}} \sin kx_5 \sin lx_6$	$-\frac{km_V}{\pi N_{k,l}} \cos kx_5 \sin lx_6$	$-\frac{lm_V}{\pi N_{k,l}} \sin kx_5 \cos lx_6$

where $N_{k,l} = \sqrt{(k^2 + l^2)(k^2 + l^2 + m_V^2)}$.

3.6.2 Electroweak gauge bosons at the $(1, 0)$ and $(0, 1)$ tiers

For scalar gauge bosons in the tiers $(n, 0)$ and $(0, n)$ with n odd, neglecting the localized operators, the correction to the neutral boson mass can be written as:

$$\begin{pmatrix} W_n^3 & B_n \end{pmatrix} \cdot \begin{pmatrix} \delta m_W^2 + m_W^2 & -\tan \theta_W m_W^2 \\ -\tan \theta_W m_W^2 & \delta m_B^2 + \tan^2 \theta_W m_W^2 \end{pmatrix} \cdot \begin{pmatrix} W_n^3 \\ B_n \end{pmatrix}. \quad (3.48)$$

Note that neither the Higgs VEV nor the loop corrections mix the two degenerate tiers. Analogously to the SM, this matrix can be diagonalized by

$$\begin{pmatrix} Z_n \\ A_n \end{pmatrix} = \begin{pmatrix} \cos \theta_n & \sin \theta_n \\ -\sin \theta_n & \cos \theta_n \end{pmatrix} \cdot \begin{pmatrix} W_n^3 \\ B_n \end{pmatrix}; \quad (3.49)$$

with mass eigenstates

$$m_{A_n, Z_n}^2 = \frac{n^2}{R^2} + \frac{1}{2} \left(m_Z^2 + \delta m_B^2 + \delta m_W^2 \mp \sqrt{(m_Z^2 + \delta m_B^2 - \delta m_W^2)^2 - 4m_W^2(\delta m_B^2 - \delta m_W^2)} \right); \quad (3.50)$$

and mixing angle

$$\tan \theta_n = \frac{m_{Z_n}^2 - m_{A_n}^2 + m_Z^2 - 2m_W^2 + \delta m_B^2 - \delta m_W^2}{2m_W m_Z \sin \theta_W}. \quad (3.51)$$

Note that the mixing angle would be equal to the SM Weinberg angle if $\delta m_B^2 = \delta m_W^2$; also, due to the fact that the loop corrections grow with the KK mass scale, for large m_{KK} the mixing angle becomes smaller. A plot of the mixing angle as a function of m_{KK} for the lightest tier is presented in Figure 3, while the splittings are plotted in Figure 4. The effect of the localized kinetic terms is easy to include: due to the fact that the bulk contributions (loops and Higgs VEV) are the same for the $(n, 0)$ and $(0, n)$ tier, they stay diagonal also in the basis $(0, n)_\pm$. Therefore, the mass eigenvalues and mixing angle are given by the same formulas as before, with $\delta m_{B,W}^2 \rightarrow \delta m_{B,W}^2 + \frac{n^2 r_{2\pi}^{B,W}}{\pi^2 \Lambda^2}$ for $(0, n)_+$ and $\delta m_{B,W}^2 \rightarrow \delta m_{B,W}^2 + \frac{n^2 r_{20}^{B,W}}{\pi^2 \Lambda^2}$ for $(0, n)_-$.

For the charged weak boson, one obtains:

$$m_{W^+}^2 = \frac{n^2}{R^2} + \delta m_W^2 + m_W^2; \quad (3.52)$$

the contribution of the localized kinetic terms can be added in the same way as for the neutral bosons.

Similar formulas apply for the vector states in the $(n, 0)$ and $(0, n)$ tiers, with n even, and to the (k, l) level: however, one needs to take into account the loop-induced mixing between the vector and the scalars, therefore the gauge fixing must be redefined at 1-loop.

Figure 3: Left panel: mixing angle $\sin \theta_1$ between the weak gauge scalars as a function of m_{KK} . For zero KK mass we obtain the SM value, for large masses the mixing angle vanishes. Right panel: mixing angle in the top sector.

3.6.3 Fermions

The Yukawa couplings are only relevant for the top, therefore we will focus on this case, while the other fermions can be obtained by a simple generalization. The Yukawa couplings can be written as:

$$\begin{aligned}
 S_{\text{Yukawa}} &= - \int dx_5 dx_6 Y_6 \bar{\Psi}_Q H \Psi_U + h.c. = \\
 &= - \int dx_5 dx_6 Y_6 [\eta_{Q+} H \chi_{U-} + \eta_{Q-} H \chi_{U+} + \bar{\chi}_{Q+} H \bar{\eta}_{U-} + \bar{\chi}_{Q-} H \bar{\eta}_{U+}] + h.c.
 \end{aligned} \tag{3.53}$$

This term can only be written if $p_r(Q) = -p_r(U)$. Plugging in the wave functions, and denoting by $q_{l/r}^{(k,l)}$ and $u_{l/r}^{(k,l)}$ the left and right-handed components of the (k, l) KK mode, we obtain the corrections to the masses. For the zero modes:

$$\mathcal{L}_{\text{Yukawa}(0,0)} = - \frac{p_g(Q) + p_g(U)}{2} \frac{Y_6 v_6}{\sqrt{2}} \bar{q}_l^{(0,0)} u_r^{(0,0)} + h.c., \tag{3.54}$$

it is clear that this term is non-vanishing only if the two bulk fermions have the same parity under the glide $p_g(Q) = p_g(U) = p_g$, and

$$m_{\text{top}} = p_g \frac{Y_6 v_6}{\sqrt{2}}. \tag{3.55}$$

For $(l, 0)$ and $(0, l)$ modes, we obtain

$$\mathcal{L}_{\text{Yukawa}(1,0)-(0,1)} = -(-1)^l m_{\text{top}} (\bar{q}_l u_r - \bar{q}_r u_l) + h.c.. \tag{3.56}$$

For the (k, l) modes, the situation is more complicated due to the presence of 2 degenerate states: the mass term can be written in general as

$$\begin{aligned}
 \mathcal{L}_{\text{Yukawa}(k,l)} &= -(-1)^{k+l} m_{\text{top}} (\cos \alpha_Q \cos \alpha_U - \sin \alpha_Q \sin \alpha_U) \\
 &\quad \left(\bar{q}_l^{(k,l)} u_r^{(k,l)} - \bar{q}_r^{(k,l)} u_l^{(k,l)} \right) + h.c.; \tag{3.57}
 \end{aligned}$$

Figure 4: Mass splitting between the different states in the tier 1 as a function of m_{KK} : in black the scalar photon (LLP), in blue the W and Z , in solid red the gluon, in green the leptons, in magenta the light quarks, in dashed red the tops.

where the two choices $\alpha_{Q/U} = \theta_{Q/U}, \pi/2 + \theta_{Q/U}$ label the four independent states, and $\theta_{Q/U}$ are arbitrary parameters. If we chose $\theta_Q = -\theta_U$, two sets of states decouple so that there are no off-diagonal mass entries, and the mass matrices reduce to

$$\mathcal{L}_{\text{Yukawa}(k,l)} = -(-1)^{k+l} m_{\text{top}} \left(\bar{q}_l^{(k,l)} u_r^{(k,l)} - \bar{q}_r^{(k,l)} u_l^{(k,l)} \right) + h.c.. \quad (3.58)$$

This is therefore a general expression valid for all modes. To find the mass eigenstates, we need to take into account the loop corrections to the Q and U masses. For the $(1,0)$ and $(0,1)$ tiers:

$$\mathcal{L}_{\text{mass}} = - \begin{pmatrix} \bar{q}_l & \bar{u}_l \end{pmatrix} \cdot \begin{pmatrix} \frac{1}{R} + \delta m_Q & -m_{\text{top}} \\ m_{\text{top}} & \frac{1}{R} + \delta m_U \end{pmatrix} \cdot \begin{pmatrix} q_r \\ u_r \end{pmatrix} + h.c.. \quad (3.59)$$

The mass eigenvalues are

$$m_{t1/2}^2 = \frac{1}{R^2} + m_{\text{top}}^2 + \delta m_Q \left(\frac{1}{R} + \frac{1}{2} \delta m_Q \pm B \right) + \delta m_U \left(\frac{1}{R} + \frac{1}{2} \delta m_U \mp B \right), \quad (3.60)$$

with

$$B = \sqrt{\left(\frac{1}{R} + \frac{\delta m_Q + \delta m_U}{2} \right)^2 + m_{\text{top}}^2}. \quad (3.61)$$

The eigenstates are given by

$$\begin{pmatrix} t_{1l,r} \\ t_{2l,r} \end{pmatrix} = \begin{pmatrix} \cos \alpha_t & \pm \sin \alpha_t \\ \mp \sin \alpha_t & \cos \alpha_t \end{pmatrix} \begin{pmatrix} q_{l,r} \\ u_{l,r} \end{pmatrix}, \quad (3.62)$$

and

$$\tan \alpha_t = B - \left(\frac{1}{R} + \frac{\delta m_Q + \delta m_U}{2} \right). \quad (3.63)$$

4 Dark Matter and collider phenomenology

The KK mass, and the Higgs mass, are the main free parameters of the model: calculating the relic Dark Matter abundance in this model, one can pin down the cosmologically interesting range for the KK mass. However, this is nothing but an estimate, because the result is very sensitive to the model of Cosmology and values of the cosmological parameters. In this work, we will assume the standard model of Cosmology and use the approximate formulas in Ref. [4]. A novel feature with respect to previous works in 6D [4, 15] is the smaller splitting between the states in the lightest tiers of resonances; therefore, we cannot neglect the co-annihilation with other particles species in the tier [16]. An average annihilation cross section can therefore be used to estimate the freeze out temperature and the relic density, assuming that all the particle species will decay into the LLP after freeze out. In our calculation, we will neglect electroweak symmetry breaking effects besides the mixing angle in the weak gauge boson sector which plays an important role in the calculation due to the relatively small mass splitting between the dark matter candidate and the heavier weak gauge resonances. We also included the main annihilation cross section between all the states in the lightest tier, and assume that the localized kinetic terms are negligible (therefore we only included the loop and Higgs contribution to the splittings). A more detailed study is left for a future publication. The result for the relic abundance as a function of the KK mass is summarized in figure 5: taking into account the presence of two degenerate tiers (1, 0) and (0, 1), we find

$$200 \text{ GeV} < m_{KK} < 300 \text{ GeV}; \quad (4.1)$$

and a limit $m_{KK} < 400 \text{ GeV}$ from the over-closure of the Universe. Note that the two degenerate tiers may be split in the case of asymmetric radii: when one radius is smaller than the other by more than few percent (in particular if the difference in mass is larger than the freeze out temperature, which is typically of order 4% of the KK mass) the heavier tier does not contribute significantly to the relic abundance and we obtain a range

$$300 \text{ GeV} < m_{KK} < 400 \text{ GeV}. \quad (4.2)$$

Note also that the mass range can be drastically modified by the localized kinetic terms: for instance, lowering the scalar gluon mass will increase the average cross section, and therefore push the preferred mass range to higher values. However, the presence of such largish

Figure 5: Relic abundance of the Dark Matter candidate as a function of m_{KK} for degenerate $(1, 0)$ and $(0, 1)$ levels (solid blue), and for the asymmetric case (dashed red).

terms will also change the splittings of other levels, and modify the branching fractions into SM particles: we will not pursue this possibility any further at present. It is interesting to compare the preferred range with the results in Ref. [15], where the chiral square is considered. On the chiral square, the splittings are larger than in our case, therefore the lightest state is to a good approximation a purely $U(1)$ hypercharge gauge scalar: because of this, the annihilation cross section is smaller, and the preferred mass range is lighter (for comparison, for light Higgs $m_H \ll m_{KK}$, they find $m_{KK} < 200$ GeV). In our case, the mixing angle is non negligible, and therefore the annihilation cross sections are much larger due to the $SU(2)$ interactions. On the other hand, the co-annihilation with leptons (both singlet and doublet) dilutes the cross section due to the large number of leptonic degrees of freedom. Scalar gluons and quarks do not play a significant role, due to their larger mass.

The inclusion of corrections from the electroweak symmetry breaking, which are important due to the lightness of the preferred mass, and resonant annihilation via the Higgs or the $(2, 0)$ and $(0, 2)$ tiers ¹ can change significantly the range: the inclusion of those effects, together with the localized kinetic terms, in a complete numerical calculation of the relic abundance is a subject under study [17].

Another important issue is the compatibility with electroweak precision measurements [3]: in fact, following previous calculations, this low mass range may be excluded once loop corrections to precision observables are taken into account. However, a detailed calculation in this specific model has not been performed (and we leave it for a future publication); moreover, the low cutoff (naively 10 times the KK mass) means that bulk higher order

¹We thank Hiroki Yamashita for pointing this out to us.

operators, similar to the SM ones, cannot be neglected. Therefore, the prediction power of the model is very limited in this sector: this issue is common to all other models of KK Dark Matter; a more detailed analysis is nevertheless required.

In the following we will take the low mass range ($m_{KK} < 400$ GeV) as a ballpark to discuss the phenomenology of the model. The main feature of this model compared to previous ones is the relatively small mass splitting among the particles in each tier. The states in the first tier will chain decay into the LLP via tree level bulk interactions: the small energy available for the SM decay products makes their observation at the LHC challenging. Below 400 GeV, the heaviest particles are the tops, about 70 GeV heavier than the LLP. Due to the large mass of the top, the main decay channel will be $t^{(1,0)} \rightarrow bW^{(1,0)} \rightarrow bW^*A^{(1,0)}$, where the virtual W^* converts into a pair of quarks or leptons. The second heaviest particle is the scalar gluon, and it decays mainly $G^{(1,0)} \rightarrow qq^{(1,0)} \rightarrow \bar{q}qA^{(1,0)}$; the quarks from light families (from the up to the bottom) decay $q^{(1,0)} \rightarrow qA^{(1,0)}$. The final states from strongly interacting particles, therefore, will always contain 1, 2 or 3 jets and missing transverse energy, however the energy of each jet will be rather small, around 20 GeV, making their observation impossible at the LHC. The scalar W and Z will mainly decay to heavy leptons (or quarks for small masses): $W^{(1,0)} \rightarrow ll^{(1,0)} \rightarrow l\nu A^{(1,0)}$, $Z^{(1,0)} \rightarrow ll^{(1,0)} \rightarrow l^-l^+A^{(1,0)}$, while leptons will decay directly to the LLP $l^{(1,0)} \rightarrow lA^{(1,0)}$. In this case the final state contains leptons, however their typical energy will be small again, less than 20 GeV, therefore they will likely escape detection at CMS and Atlas. In the table we summarize the main decays in the mass range $200\text{GeV} < m_{KK} < 400$ GeV (where MET stands for missing transverse energy):

	$m_X - m_{LLP}$ in GeV	decay mode	final state + MET
$t^{(1,0)}$	70	$bW^{(1,0)}$	bjj $bl\nu$
$G^{(1,0)}$	40-70	$qq^{(1,0)}$	jj
$q^{(1,0)}$	20-40	$qA^{(1,0)}$	j
$W^{(1,0)}$	20	$l\nu^{(1,0)}, \nu l^{(1,0)}$	$l\nu$
$Z^{(1,0)}$	20	$ll^{(1,0)}$	ll
$l^{(1,0)}$	< 5	$lA^{(1,0)}$	l
$A^{(1,0)}$	0	-	

The second level accessible at the LHC is the (1, 1) [18], with mass $\sqrt{2}m_{KK} = 300 \div 450$ GeV. Besides chain decays similar to the ones for the lightest tier, the particles in this level can also decay to SM particles via localized interactions, only if such interactions break the extra accidental KK parity. The latter is the only decay mode for the lightest state in such level, therefore, if the level is stable, the same phenomenology as the lightest tier applies here, and the observation of such states will be very hard at the LHC. If the direct decays to SM are possible, one should easily observe resonances without missing energy. The states in this level can also be singly produced via the same small couplings that induce the decays:

as those are free parameters in the model, the single-production cross sections and branching ratios cannot be predicted and we will not comment on this level any further.

Going up in mass, the next tiers are the $(2, 0)$ and $(0, 2)$. In principle, they can decay via bulk interactions in two states from the lightest tier, therefore they would go to invisible particles at the LHC. However, because of the fact that the mass is equal to twice the mass of the lightest tier at three level, the possibility that such decays are kinematically open really depends on the loop and Higgs induced splittings, and, in general, those decays will be suppressed by the small phase space. The loops (and kinetic terms) will also induce decays directly into SM particles and single productions, therefore, neglecting the localized terms, cross sections and branching fractions for this level can be calculated. The decays into SM particles will make this level easy to observe in final states without missing energy and with many clear resonances.

The first observable missing energy signal will therefore arise at the next level, $(2, 1)$ and $(1, 2)$, with mass $\sqrt{5}m_{KK} = 450 \div 650$ GeV. They are odd under the KK parity, and due to their mass they can only decay via a loop to a tier-1 particle plus a SM one. Therefore, the signature for such states will be missing energy plus one SM particle with hundreds of GeV of energy. Higher modes will repeat this pattern of decays.

Another interesting feature of this model is the possibility of rare but spectacular signals with only one SM particle plus missing energy: this is true if the lightest tier is completely unobservable. For example, one can produce two tier-1 gluons, which radiate a hard gluon: this will generate a mono-jet plus missing energy signature [19]. Similarly, one may produce via loop coupling a $(0, 1)$ state and a $(2, 1)$ state, the latter decaying into $(0, 1)$ plus a SM state, the only visible particle in the final state. More rare but spectacular signals may involve a single charged lepton, however those will be extremely rare due to the weak cross section but effectively background free due to the apparent violation of the electric charge.

The model is being implemented in the FeynRules package [20] and it will be made publicly available, which will allow to interface the Lagrangian of the model to many Monte Carlo tools, and therefore study in detail the phenomenology simply sketched in this section.

4.1 The "5D" limit

The symmetries of the real projective plane allow to define two different radii along the two directions (this is not possible on the chiral square). Doing so, we would break the symmetry that exchanges the two directions, and remove the degeneracy between levels (n, k) and (k, n) . In particular one can take a "5D" limit by sending one of the radii, say R_6 , to zero: in this limit, the model collapses to a 5D model where the KK parity is imposed on the boundaries thanks to the extended symmetry of the 6D completion. However, the effective model still differs from the 5D case in a crucial way: the limit removes all the modes that carry momentum along the x_6 direction, so that the structure of the tiers will closely resemble the 5D case, however the field content of each level will be very different. This can be rephrased saying that in the 5D limit, the 6D physics does not completely decouple: even if the modes that carry momentum along the x_6 direction decouple from the physical spectrum, the field content and spectrum of the remaining physical particles is in general

different from the one of a 5D model. On general grounds, this is the consequence of the fact that the starting point geometry is not factorized with respect to the extra dimensions, giving rise to a “geometrical” non-decoupling of the particle content and spectrum of the theory.

Numerically the splittings can be very different from the 6D case. Nevertheless, we can estimate an indicative mass range from the asymmetric case in Figure 5, where only one of the lightest tiers is taken into account: the preferred range is 300-400 GeV. The range is lighter than in the usual UED 5D scenario (around $500 \div 600$ GeV [4]) because of the different spin of the LLP, and because of the co-annihilation with singlet and doublet leptons. The phenomenology of the model will be similar to the one of the symmetric 6D one, except for the absence of some of the levels (note that the model will appear as a “5D” one at the LHC as long as $1/R_6 > \text{few TeV}$).

This example shows that even the minimal 5D model is not unique, and its structure and phenomenology may depend crucially on the presence of more dimensions which are too small to be observed. Our model, in the asymmetric limit, is therefore the minimal 5D model where the KK parity is naturally present, and the spin of the LLP can be considered a prediction.

5 Conclusions

We presented a class of models of Dark Matter in 6D where the presence of a Dark Matter candidate does not follow by an ad-hoc discrete symmetry, but it is a direct consequence of the topology of the compactification. The real projective plane is in fact the unique orbifold in 6D that allows both for chiral fermions and the absence of fixed points/lines, the latter ensuring the presence of an unbroken parity. Such parity, a relic of 6D Lorentz invariance, is exact even after including the effect of generic higher order operators localized at the two singular points of the compact space. Even though the model looks very similar to previous proposals in 6D (the chiral square), the topology of the compact space crucially affects the loop corrections to the spectrum and the structure of localized operators. We computed the one loop splitting of the lightest level, and found that the Dark Matter candidate is a scalar photon, with a mixing angle smaller than the Weinberg angle. The main difference with the chiral square is that the splittings in mass within the level tend to be smaller, therefore one needs to take into account co-annihilation with leptons and weak gauge bosons and the weak mixing angle cannot be neglected. An estimate of the relic abundance leads to a mass range $200 < m_{KK} < 300$ GeV ($300 < m_{KK} < 400$ GeV in the asymmetric case). In this range, the splittings are such that the observation of the particles in the lightest tier is virtually impossible at the LHC as the SM decay products are too soft. Higher levels are however easy to observe, as they may decay into SM particles without missing energy. The first missing energy signals may come from the level $(2, 1)$ with mass $\sqrt{5}m_{KK}$. The small splittings also allow for rare but spectacular events with apparent charge non-conservation, like for instance mono-jet or mono-lepton plus missing energy, due to the fact that the decay products of the other quark or lepton are too soft to be detected.

The model also has a limit where one of the two dimensions is much smaller than the other, so that effectively we have one extra dimension with the KK parity imposed by the 6D completion. Even though only one extra dimension is visible, the phenomenology of the model is very different from the usual 5D case, because particle content and mass splitting are very different. In particular, the KK odd levels do not have vector fields but scalars instead, and the Higgs resonances are missing. The DM candidate would be therefore a scalar instead of a vector massive photon. This is an example of a model in extra dimensions where the presence of dimensions at energies above the TeV scale can affect drastically the phenomenology. Moreover, the 5D model we present is the minimal model of KK Dark Matter in 5D where the KK parity arises naturally, and the prediction is the different spin of the lightest stable particle.

Acknowledgments

We thank Michele Papucci for useful discussions and comments. We also thank the Ecole de Physique in Les Houches where the preliminary results of this work were presented during the workshop “Physics at TeV colliders”, II session, and where we had useful discussions with Renaud Brunelieri, Christophe Grojean, Hiroki Yamashida, Jay Wacker. A Appendix: loop corrections to the masses

The calculation of the loop corrections to the masses can be performed using three methods. First, we can use the expansion of the 6D propagator in winding modes [12]: in this way it is straightforward to renormalize the 6D kinetic terms, which corresponds to removing the contribution of the zero winding modes [13]. However, the calculation is challenging in general due to the presence of Bessel functions in the expansion. The second way is to expand in KK modes along one direction, and use the resummed 5D propagator [11] along the other: the advantage is clear when computing corrections to $(n, 0)$ modes, where conservation of momentum along the second extra direction simplifies the sum over the KK number in the propagators. Finally, one can use the usual KK expansion [13]: in this case a more sophisticated technique is required to renormalize the kinetic term.

As an illustration of the three techniques, we will detail the explicit calculation of the scalar loop “f” from Figure 2 for the A_6 scalar modes $(n, 0)$ with n odd. The results from the other loops has been calculated using at least two of those techniques.

A.1 6D winding modes method

A 6D scalar field satisfies the following equation of motion :

$$\left(-\partial_\mu\partial^\mu + \partial_5^2 + \partial_6^2\right)\phi = 0. \quad (\text{A.1})$$

It is convenient to calculate the propagator in a mixed momentum representation in the uncompactified 4D and position space along the extra directions. The propagator is therefore the Green function of the following operator

$$(p^2 + \partial_5^2 + \partial_6^2) G_S^{6D}(p, x_5 - x'_5, x_6 - x'_6) = i\delta(x_5 - x'_5)\delta(x_6 - x'_6). \quad (\text{A.2})$$

The solution [12], defining $p = \sqrt{p^2}$ and $\vec{y} = (x_5, x_6)$, is:

$$G_S^{6D}(p, \vec{y} - \vec{y}') = \frac{1}{4} H_0^{(1)}(p |\vec{y} - \vec{y}'|), \quad (\text{A.3})$$

where $H_0^{(1)}$ is the zero order Hankel function of first kind. The propagator on the real projective plane is given by [21]

$$G_S^{orb}(p, \vec{y}, \vec{y}') = \frac{1}{4} \sum_{\vec{\Omega}} \left[G_S^{6D}(p, \vec{y} - \vec{y}' + \vec{\Omega}) + p_g G_S^{6D}(p, \vec{y} - g(\vec{y}') + \vec{\Omega}) \right. \\ \left. + p_r G_S^{6D}(p, \vec{y} - r(\vec{y}') + \vec{\Omega}) + p_r p_g G_S^{6D}(p, \vec{y} - r * g(\vec{y}') + \vec{\Omega}) \right] \quad (\text{A.4})$$

where $\vec{\Omega} = (2\pi n_1, 2\pi n_2)$ with $(n_1, n_2) \in \mathbb{Z}^2$ forces translation invariance ((n_1, n_2) are the winding modes), p_r and p_g are the parities of the scalar field under rotation and glide and $f(\vec{y}')$ are the transformed of the point y' under the transformation f .

The loop correction to the A_6 propagator is given by

$$i\Pi^{66} = 2ig_6^2 C(r_s) \eta_{66} \int \frac{d^4 k}{(2\pi)^4} \int d\vec{y} G_S^{orb}(k, \vec{y}, \vec{y}) A_6^{(n,0)}(q, \vec{y}) A_6^{(n,0)}(q, \vec{y}) \\ = iN (2\pi)^2 \int d^4 k \int d\vec{y} G_S^{orb}(k, \vec{y}, \vec{y}) A_6^{(n,0)}(q, \vec{y}) A_6^{(n,0)}(q, \vec{y}) \quad (\text{A.5})$$

where $A_6^{(n,0)}(q, \vec{y}) = \frac{1}{\sqrt{2\pi}} \sin nx_5$ is the wave function of the external field, $\eta_{66} = -1$ is a metric factor and $g_6^2 = (2\pi)^2 g^2$ is the 6D gauge coupling. In the following, in order to simplify the notation, we will always omit the normalization factor $N = \frac{2g^2 C(r_s) \eta_{66}}{16\pi^4}$. The correction $i\Pi^{66}$ can be split into four terms whose signs depend on the parity of the scalar field under the symmetries of the space:

$$\Pi^{66} = \Pi_T + p_g \Pi_G + p_r \Pi_R + p_g p_r \Pi_{G'}; \quad (\text{A.6})$$

Π_T is the contribution we would obtain on a torus of same radii and it is finite after the kinetic term renormalization, the other three terms are generated by the symmetries of the orbifold and we do expect a log divergence arising in Π_R due to the fixed points of the rotation.

Torus

The torus contribution is given by the first term in eq. (A.4) plugged in eq. (A.5):

$$\begin{aligned}\Pi_T &= \frac{N}{4} 4\pi^2 \int d^4k \sum_{\vec{\Omega}} \frac{1}{4} H_0^{(1)}(k | \vec{\Omega} |) \\ &= \frac{N}{4} 4\pi^3 \int_0^\infty dk_E \sum_{(n_1, n_2) \in \mathbb{Z}^2} k_E^3 K_0(2\pi k_E \sqrt{n_1^2 + n_2^2})\end{aligned}\quad (\text{A.7})$$

where K_0 is the K-Bessel function of zero order and we have performed the Wick rotation to write the last integral in Euclidean space. The zero winding mode $(n_1, n_2) = (0, 0)$ contribution is UV divergent, however such divergence is the same we would get in the limit of un-compactified space, therefore it can be absorbed by a wave function renormalization of the 6D field. Removing the $(0, 0)$ mode from the sum and integrating in k

$$\int_0^\infty dk_E k_E^3 K_0(k_E a) = \frac{4}{a^4} \quad (\text{A.8})$$

we obtain:

$$\Pi_T = \frac{N}{4} T_6 \quad \text{with} \quad T_6 = \frac{1}{\pi} \sum_{(n_1, n_2) \neq (0, 0)} \frac{1}{(n_1^2 + n_2^2)^2} \sim 1.92. \quad (\text{A.9})$$

Glides

From the second term in the propagator eq. (A.4)

$$\Pi_G = \frac{N}{4} 4\pi^2 \int d^4k \int d\vec{y} \sum_{\vec{\Omega}} \frac{1}{4} H_0^{(1)}(k | \vec{y} - g(\vec{y}) + \vec{\Omega} |) \frac{\sin^2 nx_5}{2\pi^2}. \quad (\text{A.10})$$

As the glide does not change sign to the x_5 component, the Hankel function does not depend on x_5 and its integral will lead to the normalization of wave functions. After Wick rotating and integrating in k as before we obtain

$$\Pi_G = \frac{N}{4\pi^2} \sum_{(n_1, n_2) \in \mathbb{Z}^2} \int_0^{2\pi} dx_6 \frac{1}{((n_1 - 1/2)^2 + (x_6/\pi + n_2 - 1/2)^2)^2}, \quad (\text{A.11})$$

where we numerically checked that

$$\frac{N}{\pi^2} \sum_{(n_1, n_2) \in \mathbb{Z}^2} \int_0^\pi dx_5 \frac{1}{((n_1 - 1/2)^2 + (x_6/\pi + n_2 - 1/2)^2)^2} = 7\zeta(3). \quad (\text{A.12})$$

One obtains a similar expression for the other glide $\Pi_{G'}$, now x_6 can be easily integrated out and we are left with

$$\begin{aligned}\Pi_{G'} &= \frac{N}{4\pi^2} \sum_{(n_1, n_2) \in \mathbb{Z}^2} \int_0^{2\pi} dx_5 \frac{1 - \cos 2nx_5}{((x_5/\pi + n_1 - 1/2)^2 + (n_2 - 1/2)^2)^2} \\ &= \frac{N}{4} (7\zeta(3) + B_1(n)),\end{aligned}\quad (\text{A.13})$$

where we again numerically checked that the n -dependent term corresponds to the function in Section 3.4.

Rotation

The last contribution is coming from the rotation part: after the Wick rotation

$$\Pi_R = \frac{N}{4} 2\pi \int_0^\infty dk \int d\vec{y} \sum_{\vec{\Omega}} k^3 K_0(k |2\vec{y} + \vec{\Omega}|) \sin^2 nx_5. \quad (\text{A.14})$$

To extract the divergent part, we cut-off the 4D momentum k at a scale Λ , and numerically integrated over the compact space and summed. One can therefore show that the integral is equal to

$$\Pi_R = \frac{N}{4} n^2 \pi^2 \log \frac{\Lambda^2 + n^2}{n^2}. \quad (\text{A.15})$$

From the integral form, one can see that the divergences appear when $|2\vec{y} + \vec{\Omega}| = 0$: those points are indeed the fixed points of the rotation, i.e. the corners of the fundamental square. In his notation, their geometrical origin is clear.

A.2 6D mixed propagator method

Using the full 6D propagator is complicated by the fact that one needs to deal with Bessel functions and re-sum a double sum. On the other hand, 5D propagators can be easily handled, in fact a generic scalar propagator takes the simple form:

$$G_S^{5D}(\chi_m, y - y') = \frac{i \cos \chi_m (\pi - |y - y'|)}{2 \chi_m \sin \chi_m \pi} \quad \text{where} \quad \chi_m = \sqrt{k^2 - m^2} \quad (\text{A.16})$$

and m is the 5D mass of the scalar field. One can therefore exploit this form by expanding in KK modes along one of the extra dimensions, say x_6 , and write the 6D propagator in terms of resummed 5D propagators:

$$G_S^{6D}(k, \vec{y} - \vec{y}') = \sum_{l=-\infty}^{\infty} G_S^{5D}(\chi_l, x_5 - x'_5) f_l^*(x_6) f_l(x'_6), \quad (\text{A.17})$$

where

$$f_l(x_6) = \frac{1}{\sqrt{2\pi}} e^{ix_6 l} \quad \text{and} \quad \chi_l = \sqrt{k^2 - l^2}. \quad (\text{A.18})$$

The f_l 's are the wave functions on a circle and l the KK masses for the 5D modes. This method is extremely powerful, especially to calculate corrections for modes like the $(n, 0)$: the fact that the external fields do not carry any momentum along x_6 , together with the orthonormality of the wave functions f_l , allows to easily replace the integral in the coordinate x_6 with a sum. The orbifold propagator and the scalar loop we are considering here are given by eqs. (A.4) and (A.5). Contrary to the winding mode method, this one can be extended in a straightforward way to all the other loop diagrams.

Torus

After integrating over x_5 and x_6 , the torus contribution can be written as:

$$\Pi_T = \frac{N}{4} \int d^4k \frac{1}{2\pi} \sum_{l=-\infty}^{\infty} \frac{i \cot \chi_l \pi}{2 \chi_l}. \quad (\text{A.19})$$

To remove the UV divergence, we decided to renormalized it by regularizing each 5D KK-propagators similarly to [11], so that:

$$\Pi_T = \frac{N}{4} \int d^4k \frac{1}{2\pi} \sum_{l=-\infty}^{\infty} \frac{i \cot \chi_l \pi - 1}{2 \chi_l}. \quad (\text{A.20})$$

After Wick rotation, singling out the $l = 0$ contribution, one gets:

$$\begin{aligned} \Pi_T &= \frac{N}{4} \left(\zeta(3) + 4\pi^3 \sum_{l=1}^{\infty} \int_0^{\infty} dk_E \frac{k_E^3 \left(\coth \left[\pi \sqrt{k_E^2 + l^2} \right] - 1 \right)}{2 \sqrt{k_E^2 + l^2}} \right) \\ &= \frac{N}{4} \Delta' \quad \text{with} \quad \Delta' \simeq 1.22; \end{aligned} \quad (\text{A.21})$$

because of the improper regularization scheme, the finite part is different from the previous correct result. However, the structure is the same, thus providing a powerful way to check the results obtained with the other methods.

Glides

The contribution of the glides is finite, therefore we do not have the same issue with the renormalization which arose for the torus one. Under the glide, x_6 changes sign and therefore:

$$f_l(g(x_6)) = f_l(-x_6 + \pi) = (-1)^l f_{-l}(x_6); \quad (\text{A.22})$$

due to the orthonormality, the contribution of the $l \neq 0$ modes vanishes, and we are left with

$$\Pi_G = \frac{N}{4} \int d^4k \int_0^{2\pi} dx_5 \frac{i \cos \chi_0 (\pi - |x_5 - g(x_5)|) \sin^2(nx_5)}{2 \chi_0 \sin \chi_0 \pi} \frac{1}{2\pi^2}. \quad (\text{A.23})$$

After wick rotation, and integrating in x_5 , we obtain:

$$\Pi_G = \frac{N}{4} 2\pi^3 \int_0^{\infty} dk_E \frac{k_E^3}{k_E \sinh \pi k_E} = \frac{N}{4} 7\zeta(3), \quad (\text{A.24})$$

that agrees with the result obtained using the winding modes.

Under the second glide

$$f_l(gr(x_6)) = f_l(x_6 + \pi) = (-1)^l f_l(x_6); \quad (\text{A.25})$$

therefore all modes contribute, and a $(-1)^l$ factor appears in the sum:

$$\begin{aligned}
\Pi_{G'} &= \frac{N}{4} \int d^4k \int_0^{2\pi} dx_5 \sum_{l=-\infty}^{\infty} (-1)^l \frac{i \cos \chi_l (\pi - |x_5 - gr(x_5)|)}{2 \chi_l \sin \chi_l \pi} \frac{\sin^2(nx_5)}{2\pi^2} \\
&= \frac{N}{4} \int_0^\infty dk_E \, 2\pi^2 k_E^3 \sum_{l=-\infty}^{\infty} (-1)^l \frac{2(k_E^2 + l^2) + n^2}{(k_E^2 + l^2)(k_E^2 + l^2 + n^2)} \\
&= \frac{N}{4} \int_0^\infty dk_E \, \pi^3 \left[\frac{2k_E^2}{\sinh \pi k_E} + \frac{2k_E^3}{\sqrt{n^2 + k_E^2} \sinh(\pi \sqrt{n^2 + k_E^2})} \right] \\
&= \frac{N}{4} [7\zeta(3) + B_1(n)] .
\end{aligned} \tag{A.26}$$

where

$$B_1(n) = 2\pi^3 \int_0^\infty dp \, \frac{p^3}{\sqrt{n^2 + p^2} \sinh(\pi \sqrt{n^2 + p^2})} \tag{A.27}$$

From this expression

Rotation

Similarly to the glide, for the rotation, only the zero mode contributes:

$$\begin{aligned}
\Pi_R &= \frac{N}{4} \int d^4k \int_0^{2\pi} dx_5 \frac{i \cos \chi_0 (\pi - |x_5 - r(x_5)|)}{2 \chi_0 \sin \chi_0 \pi} \frac{\sin^2(nx_5)}{2\pi^2} \\
&= \frac{N}{4} \int d^4k \, \frac{in^2}{k^2 (n^2 - k^2)} .
\end{aligned} \tag{A.28}$$

After Wick rotation, we regularize the integral by cut off as before:

$$\Pi_R = \frac{N}{4} \int_0^\Lambda dk_E \, 2\pi^2 k_E \frac{n^2}{(n^2 + k_E^2)} = \frac{N}{4} \, n^2 \pi^2 \log \frac{\Lambda^2 + n^2}{n^2} . \tag{A.29}$$

A.3 6D Kaluza Klein expansions method

This method, the most commonly used one, makes use of the expansion in 4D KK modes, therefore one needs to compute loops with usual 4D propagators and then sum over the KK momenta of the towers. However, computing all the necessary couplings between modes can be tedious, and a Fourier transform that goes back to winding modes is necessary for the renormalization of the torus contribution. Nevertheless, this method can be easily applied to any loop structure.

Here we will again stick to one concrete example. The contribution of a scalar field with parities (p_r, p_g) can be written as

$$\Pi_{p_g \, p_r} = \Pi_T + p_g \Pi_G + p_g p_r \Pi_{G'} + p_r \Pi_R ; \tag{A.30}$$

therefore if we calculated the contribution of all 4 parity possibility, we would be able to extract each term:

$$\Pi_T = \frac{1}{4} (\Pi_{++} + \Pi_{+-} + \Pi_{-+} + \Pi_{--}) \quad (\text{A.31})$$

$$\Pi_G = \frac{1}{4} (\Pi_{++} - \Pi_{+-} + \Pi_{-+} - \Pi_{--}) \quad (\text{A.32})$$

$$\Pi_{G'} = \frac{1}{4} (\Pi_{++} - \Pi_{+-} - \Pi_{-+} + \Pi_{--}) \quad (\text{A.33})$$

$$\Pi_R = \frac{1}{4} (\Pi_{++} + \Pi_{+-} - \Pi_{-+} - \Pi_{--}) \quad (\text{A.34})$$

The couplings that enter the loop, $A_{(n,0)}^6 A_{(n,0)}^6 \phi_{(m,l)}^\dagger \phi_{(m,l)}$ are proportional to $ig^2 \eta_{66}$ with a coefficient that depends on the wave function integrals. We listed such coefficients in the following table (here $m, l \neq 0$ are intended):

$(p_r \ p_g)$	$(++)$	$(+-)$	$(-+)$	$(--)$
$(0, 0)$	2	-	-	-
$(m, 0)$ m even	2	-	2	-
$(m, 0)$ $m \neq n$ m odd	-	2	-	2
$(n, 0)$	-	1	-	3
$(0, l)$ l even	2	-	-	2
$(0, l)$ l odd	-	2	2	-
(m, l) $m \neq n$	2	2	2	2
(n, l) l even	3	1	1	3
(n, l) l odd	1	3	3	1

For example, using the previous table, the correction coming from ϕ_{++} and ϕ_{+-} running into the loop are:

$$\begin{aligned} i\Pi_{++} = N \Big(& \sum_{(m,l) \geq 1} 2G(m, l) + \sum_{l \geq 1} ((-1)^l G(n, l) + 2G(0, 2l)) \\ & + \sum_{m \geq 1, m \neq n} 2G(2m, 0) + 2G(0, 0) \Big), \end{aligned} \quad (\text{A.35})$$

$$\begin{aligned} i\Pi_{+-} = N \Big(& \sum_{(m,l) \geq 1} 2G(m, l) + \sum_{l \geq 1} (-(-1)^l G(n, l) + 2G(0, 2l - 1)) \\ & + \sum_{m \geq 1, m \neq n} 2G(2m - 1, 0) + G(n, 0) \Big); \end{aligned} \quad (\text{A.36})$$

where

$$G(m, l) = \int_0^\infty dk_E \frac{k_E^3}{k_E^2 + m^2 + l^2} \quad (\text{A.37})$$

is the integral appearing in the 4D loop.

Torus

For the torus contribution, we reconstruct a sum over all the KK modes on a torus compactification: following the usual Fourier expansion in the double sum and removing the zero winding mode contribution

$$\Pi_T = N \frac{1}{2} \sum_{(m,l) \in \mathbb{Z}^2} G(m,l) = \frac{N}{4} T_6. \quad (\text{A.38})$$

Glides

Following the same procedure, the glide contribution can be written as

$$\Pi_G = \frac{N}{4} 2 \sum_{m \in \mathbb{Z}} (-1)^m G(m,0) = \frac{N}{4} 7\zeta(3); \quad (\text{A.39})$$

while for the second glide

$$\Pi_{G'} = \frac{N}{4} 2 \sum_{l \in \mathbb{Z}} (-1)^l (G(n,l) + G(0,l)) = \frac{N}{4} (7\zeta(3) + B_1(n)). \quad (\text{A.40})$$

Rotation

For the rotation contribution, the loop calculation gives:

$$\begin{aligned} \Pi_R &= \frac{N}{4} 2 (G(0,0) - G(n,0)) = \frac{N}{4} \int_0^\Lambda dk_E \left(k_E - \frac{k_E^3}{k_E^2 + n^2} \right) \\ &= \frac{N}{4} n^2 \pi^2 \log \frac{\Lambda^2 + n^2}{n^2}. \end{aligned} \quad (\text{A.41})$$

B Appendix: loop integrals

The functions of n appearing in the loop corrections can be expressed in terms of the three following integrals:

$$\Phi_1(n) = 2\pi^3 \int_0^\infty dk \frac{k^3}{\sqrt{k^2 + n^2} \sinh \pi \sqrt{k^2 + n^2}}, \quad (\text{B.1})$$

$$\Phi_2(n) = 2\pi^3 \int_0^\infty dk \frac{kn(\sqrt{k^2 + n^2} - n)}{\sqrt{k^2 + n^2} \sinh \pi \sqrt{k^2 + n^2}}, \quad (\text{B.2})$$

$$\Phi_3(n) = 2\pi^3 \int_0^\infty dk \frac{k^3(\sqrt{k^2 + n^2} - n)}{n\sqrt{k^2 + n^2} \sinh \pi \sqrt{k^2 + n^2}}. \quad (\text{B.3})$$

Those integrals can be computed analytically, and we found

$$\Phi_1(n) = 2\pi n \phi_2(n) - \phi_3(n), \quad (\text{B.4})$$

$$\Phi_2(n) = n(\pi^3 + \pi \phi_2(n)), \quad (\text{B.5})$$

$$\Phi_3(n) = \frac{1-2n^2}{2n}\pi^3 - 2\phi_3(n) + \frac{3}{2\pi n}\phi_4(n); \quad (\text{B.6})$$

with

$$\phi_s(n) = \text{Li}_s(e^{2\pi n}) - 2^s \text{Li}_s(e^{\pi n}) - i \frac{2^{s-1}\pi^s}{\Gamma(s)} n^{s-1}, \quad (\text{B.7})$$

where Li_s is the Polylogarithmic function of order s and the imaginary term cancels the imaginary parts of the Polylogs to make a real function of n . Numerically the integrals are suppressed for large n :

	$n = 1$	$n = 2$	$n = 3$
Φ_1	1.43	0.109	0.0067
Φ_2	0.54	0.047	0.0030
Φ_3	1.02	0.037	0.0015

The functions appearing in the loop corrections are (where we report the numerical value for $n = 1$):

$$B_1 = \Phi_1 \sim 1.43, \quad (\text{B.8})$$

$$B_2 = \Phi_1 - \Phi_2 \sim 0.89, \quad (\text{B.9})$$

$$B_3 = \Phi_1 + \frac{9}{2}\Phi_2 - 3\Phi_3 \sim 1.83, \quad (\text{B.10})$$

$$F_1 = \Phi_1 - 2\Phi_2 \sim 0.35, \quad (\text{B.11})$$

$$F_2 = \Phi_2 \sim 0.54. \quad (\text{B.12})$$
